Storage: in an airtight container.

Sodium tetrahydroborate reducing solution. 1146901.

Introduce about 100 ml of *water R* into a 500 ml volumetric flask containing a stirring bar. Add 5.0 g of *sodium hydroxide R* in pellets and 2.5 g of *sodium tetrahydroborate R*. Stir until complete dissolution, dilute to 500.0 ml with *water R* and mix. Prepare immediately before use.

Sodium tetraphenylborate. $NaB(C_6H_5)_4$. (M_r 342.2). 1084400. [143-66-8].

A white or slightly yellowish, bulky powder, freely soluble in water and in acetone.

Sodium tetraphenylborate solution. 1084401.

Filter before use if necessary.

A 10 g/l solution.

Storage: use within 1 week.

Sodium thioglycollate. $C_2H_3NaO_2S$. (M_r 114.1). 1084500. [367-51-1]. Sodium mercaptoacetate.

White, granular powder or crystals, hygroscopic, freely soluble in water and in methanol, slightly soluble in alcohol.

Storage: in an airtight container.

Sodium thiosulphate. 1084600. [10102-17-7].

See *Sodium thiosulphate* (0414).

Sodium tungstate. $Na_2WO_4 \cdot 2H_2O$. (M_r 329.9). 1084700. [10213-10-2]. Disodium tungstate dihydrate.

A white, crystalline powder or colourless crystals, freely soluble in water forming a clear solution, practically insoluble in alcohol.

Sorbitol. 1084800. [50-70-4].

See *Sorbitol* (0435).

Squalane. $C_{30}H_{62}$. (M_r 422.8). 1084900. [111-01-3].
2,6,10,15,19,23-Hexamethyltetracosane.

A colourless, oily liquid, freely soluble in fatty oils, slightly soluble in acetone, in alcohol, in glacial acetic acid and in methanol.

d_{20}^{20} : 0.811 to 0.813.

n_D^{20} : 1.451 to 1.453.

Stannous chloride. $SnCl_2 \cdot 2H_2O$. (M_r 225.6). 1085000.
[10025-69-1]. Tin dichloride dihydrate.

Content: minimum 97.0 per cent of $SnCl_2 \cdot 2H_2O$.

Colourless crystals, very soluble in water, freely soluble in alcohol, in glacial acetic acid and in dilute and concentrated hydrochloric acid.

Assay. Dissolve 0.500 g in 15 ml of *hydrochloric acid R* in a ground-glass-stoppered flask. Add 10 ml of *water R* and 5 ml of *chloroform R*. Titrate rapidly with 0.05 M *potassium iodate* until the chloroform layer is colourless.

1 ml of 0.05 M *potassium iodate* is equivalent to 22.56 mg of $SnCl_2 \cdot 2H_2O$.

Stannous chloride solution. 1085001.

Heat 20 g of *tin R* with 85 ml of *hydrochloric acid R* until no more hydrogen is released. Allow to cool.

Storage: over an excess of *tin R*, protected from air.

Stannous chloride solution R1. 1085002.

Immediately before use, dilute 1 volume of *stannous chloride solution R* with 10 volumes of *dilute hydrochloric acid R*.

Stannous chloride solution R2. 1085003.

To 8 g of *stannous chloride R* add 100 ml of a 20 per cent V/V solution of *hydrochloric acid R*. Shake until dissolved, heating, if necessary, on a water-bath at 50 °C. Pass a current of *nitrogen R* for 15 min. Prepare immediately before use.

Stanolone. $C_{19}H_{30}O_2$. (M_r 290.4). 1154400. [521-18-6].
17 β -Hydroxy-5 α -androstan-3-one.

White or almost white powder.

mp: about 180 °C.

Standard solution for the micro determination of water. 1147300.

Commercially available standard solution for the coulometric titration of water, containing a certified content of water in a suitable solvent.

Staphylococcus aureus strain V8 protease. Type XVII-B. 1115800. [66676-43-5].

Microbial extracellular proteolytic enzyme. A lyophilised powder containing 500 units to 1000 units per milligram of solid.

Starch, soluble. 1085100. [9005-84-9].

A white powder.

Prepare a 20 g/l solution in hot *water R*. The solution is at most slightly opalescent and remains fluid on cooling.

Starch iodate paper. 1085101.

Immerse strips of filter paper in 100 ml of *iodide-free starch solution R* containing 0.1 g of *potassium iodate R*. Drain and allow to dry protected from light.

Starch iodide paper. 1085106.

Immerse strips of filter paper in 100 ml of *starch solution R* containing 0.5 g of *potassium iodide R*. Drain and allow to dry protected from light.

Test for sensitivity. Mix 0.05 ml of 0.1 M *sodium nitrite* with 4 ml of *hydrochloric acid R* and dilute to 100 ml with *water R*. Apply one drop of the solution to starch iodide paper; a blue spot appears.

Starch solution. 1085103.

Triturate 1.0 g of *soluble starch R* with 5 ml of *water R* and whilst stirring pour the mixture into 100 ml of boiling *water R* containing 10 mg of *mercuric iodide R*.

Carry out the test for sensitivity each time the reagent is used.

Test for sensitivity. To a mixture of 1 ml of the starch solution and 20 ml of *water R*, add about 50 mg of *potassium iodide R* and 0.05 ml of *iodine solution R1*. The solution is blue.

Starch solution, iodide-free. 1085104.

Prepare the solution as prescribed for *starch solution R* omitting the mercuric iodide. Prepare immediately before use.

Starch solution R1. 1085105.

Mix 1 g of *soluble starch R* and a small amount of cold *water R*. Add this mixture, while stirring, to 200 ml of boiling *water R*. Add 250 mg of *salicylic acid R* and boil for 3 min. Immediately remove from the heat and cool.

Storage: long storage is required, the solution shall be stored at 4 °C to 10 °C. A fresh starch solution shall be prepared when the end-point of the titration from blue to colourless fails to be sharp. If stored under refrigeration, the starch solution is stable for about 2 to 3 weeks.

Test for sensitivity. A mixture of 2 ml of *starch solution R1*, 20 ml of *water R*, about 50 mg of *potassium iodide R* and 0.05 ml of *iodine solution R1* is blue.

Starch solution R2. 1085107.

Triturate 1.0 g of *soluble starch R* with 5 ml of *water R* and whilst stirring pour the mixture into 100 ml of boiling *water R*. Use a freshly prepared solution.

Test for sensitivity. To a mixture of 1 ml of the starch solution and 20 ml of *water R*, add about 50 mg of *potassium iodide R* and 0.05 ml of *iodine solution R1*. The solution is blue.

Stearic acid. $C_{18}H_{36}O_2$. (M_r 284.5). 1085200. [57-11-4].
Octadecanoic acid.

White powder or flakes, greasy to the touch, practically insoluble in water, soluble in hot alcohol.

mp: about 70 °C.

Stearic acid used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit (1848)*. The content of stearic acid is not less than 98 per cent, calculated by the normalisation procedure.

Stearyl alcohol. $C_{18}H_{38}O$. (M_r 270.5). 1156400. [112-92-5].
1-Octadecanol.

mp: about 60 °C.

Content: minimum 95 per cent of $C_{18}H_{38}O$.

Stigmasterol. $C_{29}H_{48}O$. (M_r 412.7). 1141400. [83-48-7]. (22*E*)-Stigmasta-5,22-dien-3 β -ol.
(22*E*)-24-Ethylcholesta-5,22-dien-3 β -ol.

White powder, insoluble in water.

mp: about 170 °C.

$[\alpha]_D^{22}$: about – 51 ($c = 2$ in chloroform).

Streptomycin sulphate. 1085300. [3810-74-0].

See *Streptomycin sulphate* (0053).

Strongly acidic ion-exchange resin. 1085400.

See *ion-exchange resin, strongly acidic R*.

Strontium carbonate. SrCO_3 . (M_r 147.6). 1122700. [1633-05-2].

A white, crystalline powder.

Content: minimum 99.5 per cent of SrCO_3 .

Styrene. C_8H_8 . (M_r 104.2). 1151700. [100-42-5].
Ethenylbenzene.

bp: about 145 °C.

Colourless, oily liquid, very slightly soluble in water.

Styrene-divinylbenzene copolymer. 1085500.

Porous, rigid, cross-linked polymer beads. Several grades are available with different sizes of beads. The size range of the beads is specified after the name of the reagent in the tests where it is used.

Succinic acid. $\text{C}_4\text{H}_6\text{O}_4$. (M_r 118.1). 1085600. [110-15-6].
Butanedioic acid.

A white, crystalline powder or colourless crystals, soluble in water and in alcohol.

mp: 184 °C to 187 °C.

Sucrose. 1085700. [57-50-1].

See *Sucrose* (0204).

When sucrose is used for controlling the polarimeter, it must be kept dry in a sealed ampoule.

Sudan orange. $\text{C}_{16}\text{H}_{12}\text{N}_2\text{O}$. (M_r 248.3). 1110700. [842-07-9].
Colour Index No. 12055.

1-(Phenylazo)naphthalen-2-ol. Sudan I.

An orange-red powder, practically insoluble in water, soluble in methylene chloride.

mp: about 131 °C.

Sudan red G. $\text{C}_{17}\text{H}_{14}\text{N}_2\text{O}_2$. (M_r 278.3). 1085800.

Schultz No. 149.

Colour Index No. 12150.

Solvent Red 1. 1-[(2-Methoxyphenyl)azo]naphthalen-2-ol.

A reddish-brown powder, practically insoluble in water.

Chromatography. Examine by thin-layer chromatography (2.2.27) using *silica gel G R* as the coating substance. Apply 10 µl of a 0.1 g/l solution in *methylene chloride R* and develop over a path of 10 cm with the same solvent. The chromatogram shows only one principal spot.

Sulfanilamide. $\text{C}_6\text{H}_8\text{N}_2\text{O}_2\text{S}$. (M_r 172.2). 1086100. [63-74-1].
4-Aminobenzenesulphonamide.

A white powder, slightly soluble in water, freely soluble in boiling water, in acetone, in dilute acids and in solutions of the alkali hydroxides, sparingly soluble in alcohol and in light petroleum.

mp: about 165 °C.

Sulphamic acid. $\text{H}_3\text{NO}_3\text{S}$. (M_r 97.1). 1085900. [5329-14-6].

White crystalline powder or crystals, freely soluble in water, sparingly soluble in acetone, in alcohol and in methanol.

mp: about 205 °C, with decomposition.

Sulphan blue. $\text{C}_{27}\text{H}_{31}\text{N}_2\text{NaO}_6\text{S}_2$. (M_r 566.6). 1086000. [129-17-9].

Schultz No. 769.

Colour Index No. 42045.

Acid Blue 1. Patent Blue VF. Disulphine blue.

Blue VS. Sodium [[[(4-diethylamino)phenyl](2,4-disulphonatophenyl)methylene]cyclohexa-2,5-dien-1-ylidene]diethylammonium.

A violet powder, soluble in water. Dilute solutions are blue and turn yellow on the addition of concentrated hydrochloric acid.

Sulphanilic acid. $\text{C}_6\text{H}_7\text{NO}_3\text{S}$. (M_r 173.2). 1086200. [121-57-3]. 4-Aminobenzenesulphonic acid.

Colourless crystals, sparingly soluble in water, practically insoluble in alcohol.

Sulphanilic acid solution. 1086203.

Dissolve 0.33 g of *sulphanilic acid R* in 75 ml of *water R* heating gently if necessary and dilute to 100 ml with *glacial acetic acid R*.

Sulphanilic acid solution R1. 1086201.

Dissolve 0.5 g of *sulphanilic acid R* in a mixture of 75 ml of *dilute acetic acid R* and 75 ml of *water R*.

Sulphanilic acid solution, diazotised. 1086202.

Dissolve, with warming, 0.9 g of *sulphanilic acid R* in 9 ml of *hydrochloric acid R*, and dilute to 100 ml with *water R*. Cool 10 ml of this solution in iced water and add 10 ml of an ice-cold 4.5 per cent *m/V* solution of *sodium nitrite R*. Allow to stand at 0 °C for 15 min (if stored at this temperature, the solution is stable for 3 days) and immediately before use add 20 ml of a 10 per cent *m/V* solution of *sodium carbonate R*.

Sulfathiazole. $\text{C}_9\text{H}_9\text{N}_3\text{O}_2\text{S}_2$. (M_r 255.3). 1086300. [72-14-0].
4-Amino-*N*-(thiazol-2-yl)benzenesulphonamide.

White or yellowish-white powder or crystals, very slightly soluble in water, soluble in acetone, slightly soluble in alcohol. It dissolves in dilute mineral acids and in solutions of alkali hydroxides and carbonates.

mp: about 200 °C.

Sulphomolybdic reagent R2. 1086400.

Dissolve about 50 mg of *ammonium molybdate R* in 10 ml of *sulphuric acid R*.

Sulphomolybdic reagent R3. 1086500.

Dissolve with heating 2.5 g of *ammonium molybdate R* in 20 ml of *water R*. Dilute 28 ml of *sulphuric acid R* in 50 ml of *water R*, then cool. Mix the two solutions and dilute to 100 ml with *water R*.

Storage: in a polyethylene container.

Sulphosalicylic acid. $\text{C}_7\text{H}_6\text{O}_6\text{S}_2\text{H}_2\text{O}$. (M_r 254.2). 1086600. [5965-83-3]. 2-Hydroxy-5-sulphobenzoic acid.

A white, crystalline powder or crystals, very soluble in water and in alcohol.

mp: about 109 °C.

Sulphur. 1110800. [7704-34-9].

See *Sulphur for external use* (0953).

Sulphur dioxide. SO_2 . (M_r 64.1). 1086700. [7446-09-5].
Sulphurous anhydride.

A colourless gas. When compressed it is a colourless liquid.

Sulphur dioxide R1. SO_2 . (M_r 64.1). 1110900.

Content: minimum 99.9 per cent *V/V* of SO_2 .

Sulphuric acid. H_2SO_4 . (M_r 98.1). 1086800. [7664-93-9].

Content: 95.0 per cent *m/m* to 97.0 per cent *m/m* of H_2SO_4 .

A colourless, caustic liquid with an oily consistency, highly hygroscopic, miscible with water and with alcohol producing intense heat.

d_{20}^{20} : 1.834 to 1.837.

A 10 g/l solution is strongly acid and gives the reactions of sulphates (2.3.1).

Appearance. It is clear (2.2.1) and colourless (2.2.2, Method II).

Oxidisable substances. Pour 20 g cautiously, with cooling, into 40 ml of *water R*. Add 0.5 ml of 0.002 M *potassium permanganate*. The violet colour persists for at least 5 min.

Chlorides. Pour 10 g, carefully and while cooling, into 10 ml of *water R* and after cooling dilute to 20 ml with the same solvent. Add 0.5 ml of *silver nitrate solution R2*. Allow to stand for 2 min protected from bright light. The solution is not more opalescent than a standard prepared at the same time using a mixture of 1 ml of *chloride standard solution (5 ppm Cl) R*, 19 ml of *water R* and 0.5 ml of *silver nitrate solution R2* (0.5 ppm).

Nitrates. Pour 50 g or 27.2 ml, carefully and while cooling, into 15 ml of *water R*. Add 0.2 ml of a freshly prepared 50 g/l solution of *brucine R* in *glacial acetic acid R*. After 5 min any colour is less intense than that of a reference mixture prepared in the same manner and containing 12.5 ml of *water R*, 50 g of *nitrogen-free sulphuric acid R*, 2.5 ml of *nitrate standard solution (10 ppm NO₃) R* and 0.2 ml of a 50 g/l solution of *brucine R* in *glacial acetic acid R* (0.5 ppm).

Ammonium. Pour 2.5 g, carefully and while cooling, into *water R* and dilute to 20 ml with the same solvent. Cool, and add dropwise 10 ml of a 200 g/l solution of *sodium hydroxide R*, followed by 1 ml of *alkaline potassium tetraiodomercurate solution R*. The colour of the solution is less intense than that of a mixture of 5 ml of *ammonium standard solution (1 ppm NH₄) R*, 15 ml of *water R*, 10 ml of a 200 g/l solution of *sodium hydroxide R* and 1 ml of *alkaline potassium tetraiodomercurate solution R* (2 ppm).

Arsenic (2.4.2). To 50 g add 3 ml of *nitric acid R* and evaporate carefully until the volume is reduced to about 10 ml. Cool, add to the residue 20 ml of *water R* and concentrate to 5 ml. The solution complies with limit test A for arsenic (0.02 ppm). Prepare the standard using 1.0 ml of *arsenic standard solution (1 ppm As) R*.

Heavy metals (2.4.8). Dilute 10 ml of the solution obtained in the test for iron to 20 ml with *water R*. 12 ml of the solution complies with limit test A for heavy metals (2 ppm). Prepare the standard using *lead standard solution (2 ppm Pb) R*.

Iron (2.4.9). Dissolve the residue on ignition with slight heating in 1 ml of *dilute hydrochloric acid R* and dilute to 50.0 ml with *water R*. 5 ml of the solution diluted to 10 ml with *water R* complies with the limit test for iron (1 ppm).

Residue on ignition: maximum 0.001 per cent, determined on 100 g by evaporating cautiously in a small crucible over a naked flame and igniting the residue to redness.

Assay. Weigh accurately a ground-glass-stoppered flask containing 30 ml of *water R*, introduce 0.8 ml of the sulphuric acid, cool and weigh again. Titrate with 1 M *sodium hydroxide*, using 0.1 ml of *methyl red solution R* as indicator.

1 ml of 1 M *sodium hydroxide* is equivalent to 49.04 mg of H₂SO₄.

Storage: in a ground-glass-stoppered container made of glass or other inert material.

Sulphuric acid, alcoholic, 2.5 M. 1086801.

Carefully and with constant cooling, stir 14 ml of *sulphuric acid R* into 60 ml of *ethanol R*. Allow to cool and dilute to 100 ml with *ethanol R*. Prepare immediately before use.

Sulphuric acid, alcoholic, 0.25 M. 1086802.

Dilute 10 ml of 2.5 M *alcoholic sulphuric acid R* to 100 ml with *ethanol R*. Prepare immediately before use.

Sulphuric acid, alcoholic solution of. 1086803.

Carefully and with constant cooling, stir 20 ml of *sulphuric acid R* into 60 ml of *alcohol R*. Allow to cool and dilute to 100 ml with *alcohol R*. Prepare immediately before use.

Sulphuric acid, dilute. 1086804.

Contains 98 g/l of H₂SO₄.

Add 5.5 ml of *sulphuric acid R* to 60 ml of *water R*, allow to cool and dilute to 100 ml with the same solvent.

Assay. Into a ground-glass-stoppered flask containing 30 ml of *water R*, introduce 10.0 ml of the dilute sulphuric acid. Titrate with 1 M *sodium hydroxide*, using 0.1 ml of *methyl red solution R* as indicator.

1 ml of 1 M *sodium hydroxide* is equivalent to 49.04 mg of H₂SO₄.

Sulphuric acid-formaldehyde reagent. 1086805.

Mix 2 ml of *formaldehyde solution R* with 100 ml of *sulphuric acid R*.

Sulphuric acid, heavy metal-free. 1086807.

Complies with the requirements prescribed for *sulphuric acid R* and with the following maximum contents of heavy metals:

As: 0.005 ppm;

Cd: 0.002 ppm;

Cu: 0.001 ppm;

Fe: 0.05 ppm;

Hg: 0.005 ppm;

Ni: 0.002 ppm;

Pb: 0.001 ppm;

Zn: 0.005 ppm.

Sulphuric acid, nitrogen-free. 1086806.

Complies with the requirements prescribed for *sulphuric acid R* and with the following additional test.

Nitrates. To 5 ml of *water R* add carefully 45 ml of the sulphuric acid, allow to cool to 40 °C and add 8 mg of *diphenylbenzidine R*. The solution is faint pink or very pale blue.

Sulphuric acid, nitrogen-free R1. 1086808.

Nitrogen-free sulphuric acid R containing 95.0 per cent *m/m* to 95.5 per cent *m/m* of H₂SO₄.

Sunflower oil. 1086900.

See *Sunflower oil, refined (1371)*.

Tagatose. C₆H₁₂O₆. (*M_r* 180.16). 1111000. [87-81-0]. D-lyxo-Hexulose.

White powder.

$[\alpha]_D^{20}$: -2.3 (21.9 g/l solution in *water R*).

mp: 134 °C to 135 °C.

Talc. 1087000. [14807-96-6].

See *Talc (0438)*.

Tannic acid. 1087100. [1401-55-4].

Yellowish to light-brown, glistening scales or amorphous powder, very soluble in water, freely soluble in alcohol, soluble in acetone.

Storage: protected from light.

Tartaric acid. 1087200. [87-69-4].

See *Tartaric acid* (0460).

Taxifolin. C₁₅H₁₂O₇. (*M_r* 304.3). 1151800. [480-18-2]. (2*R*,3*R*)-2-(3,4-Dihydroxyphenyl)-3,5,7-trihydroxy-2,3-dihydro-4*H*-1-benzopyran-4-one.

White or almost white powder, slightly soluble in ethanol.

A solution in *ethanol R* shows an absorption maximum (2.2.25) at 290 nm.

Tecnazene. C₆HCl₄NO₂. (*M_r* 260.9). 1132400. [117-18-0].

bp: about 304 °C.

mp: 99 °C to 100 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

α-Terpinene. C₁₀H₁₆. (*M_r* 136.2). 1140300. [99-86-5]. 1-Isopropyl-4-methylcyclohexa-1,3-diene.

Clear, almost colourless liquid.

*d*₄²⁰: about 0.837.

*n*_D²⁰: about 1.478.

bp: about 174 °C.

α-Terpinene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Tea tree oil* (1837).

The content is not less than 95 per cent, calculated by the normalisation procedure.

γ-Terpinene. C₁₀H₁₆. (*M_r* 136.2). 1115900. [99-85-4]. 1-Isopropyl-4-methylcyclohexa-1,4-diene.

An oily liquid.

*d*₄¹⁵: about 0.850.

*n*_D¹⁵: 1.474 to 1.475.

bp: 183 °C to 186 °C.

γ-Terpinene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph *Peppermint oil* (0405).

Test solution. The substance to be examined.

The area of the principal peak is not less than 93.0 per cent of the area of all the peaks in the chromatogram obtained.

Terpinen-4-ol. C₁₀H₁₈O. (*M_r* 154.2). 1116000. [562-74-3]. 4-Methyl-1-(1-methylethyl)cyclohex-3-en-1-ol. *p*-Menth-1-en-4-ol.

An oily, colourless liquid.

*d*₂₀²⁰: about 0.934.

*n*_D²⁰: about 1.477.

bp: 209 °C to 212 °C.

Terpinen-4-ol used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Lavender oil* (1338).

Test solution. The substance to be examined.

The area of the principal peak is not less than 98.0 per cent of the area of all the peaks in the chromatogram obtained.

α-Terpineol. C₁₀H₁₈O. (*M_r* 154.2). 1087300. [98-55-5]. (2*S*)-2-(4-Methylcyclohex-3-enyl)-2-propanol.

Colourless crystals, practically insoluble in water, soluble in alcohol.

*d*₂₀²⁰: about 0.935.

*n*_D²⁰: about 1.483.

[α]_D²⁰: about 92.5.

mp: about 35 °C.

It may contain 1 to 3 per cent of β-terpineol.

α-Terpineol used in gas chromatography complies with the following test.

Assay. Examine by gas chromatography (2.2.28) under the conditions described in the monograph on *Anise oil* (0804).

Test solution. A 100 g/l solution in *hexane R*.

The area of the principal peak is not less than 97.0 per cent of the total area of the peaks. Disregard the peak due to hexane.

Terpinolene. C₁₀H₁₆. (*M_r* 136.2). 1140400. [586-62-9]. *p*-Mentha-1,4(8)-diene. 4-Isopropylidene-1-methylcyclohexene.

Clear, almost colourless liquid.

*d*₄²⁰: about 0.863.

*n*_D²⁰: about 1.488.

bp: about 184 °C.

Terpinolene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Tea tree oil* (1837).

The content is not less than 90 per cent, calculated by the normalisation procedure.

Testosterone. 1116100. [58-22-0].

See *Testosterone* (1373).

Testosterone propionate. 1087400. [57-85-2].

See *Testosterone propionate* (0297).

Tetrabutylammonium bromide. C₁₆H₃₆BrN. (*M_r* 322.4). 1087500. [1643-19-2].

White or almost white crystals.

mp: 102 °C to 104 °C.

Tetrabutylammonium dihydrogen phosphate. C₁₆H₃₈NO₄P. (*M_r* 339.5). 1087600. [5574-97-0].

White powder, hygroscopic.

pH (2.2.3): about 7.5 for a 170 g/l solution.

Absorbance (2.2.25): about 0.10 determined at 210 nm using a 170 g/l solution.

Storage: in an airtight container.

Tetrabutylammonium hydrogen sulphate. C₁₆H₃₇NO₄S. (*M_r* 339.5). 1087700. [32503-27-8].

A crystalline powder or colourless crystals, freely soluble in water and in methanol.

mp: 169 °C to 173 °C.

Absorbance (2.2.25). The absorbance of a 50 g/l solution, at wavelengths from 240 nm to 300 nm, is not greater than 0.05.

Tetrabutylammonium hydrogen sulphate R1. 1087701.

Complies with the requirements prescribed for *tetrabutylammonium hydrogen sulphate R* and with the following additional requirement:

Absorbance (2.2.25). The absorbance of a 50 g/l solution, at wavelengths from 215 nm to 300 nm, is not greater than 0.02.

Tetrabutylammonium hydroxide. $C_{16}H_{37}NO \cdot 30H_2O$. (M_r 800). 1087800. [2052-49-5].

Content: minimum 98.0 per cent of $C_{16}H_{37}NO \cdot 30H_2O$.

White or almost white crystals, soluble in water.

Assay. Dissolve 1.000 g in 100 ml of *water R*. Titrate immediately with 0.1 M *hydrochloric acid* determining the end-point potentiometrically (2.2.20). Carry out a blank titration.

1 ml of 0.1 M *hydrochloric acid* is equivalent to 80.0 mg $C_{16}H_{37}NO \cdot 30H_2O$.

Tetrabutylammonium hydroxide solution (104 g/l). 1087801. [2052-49-5].

A solution containing 104 g/l of $C_{16}H_{37}NO$ (M_r 259.5), prepared by dilution of a suitable reagent grade.

Tetrabutylammonium hydroxide solution (400 g/l). 1087802. [2052-49-5].

A solution containing 400 g/l of $C_{16}H_{37}NO$ (M_r 259.5) of a suitable grade.

Tetrabutylammonium iodide. $C_{16}H_{36}IN$. (M_r 369.4). 1087900. [311-28-4].

Content: minimum 98.0 per cent of $C_{16}H_{36}IN$.

White or slightly coloured, crystalline powder or crystals, soluble in alcohol.

Sulphated ash (2.4.14): maximum 0.02 per cent.

Assay. Dissolve 1.200 g in 30 ml of *water R*. Add 50.0 ml of 0.1 M *silver nitrate* and 5 ml of *dilute nitric acid R*. Titrate the excess of silver nitrate with 0.1 M *ammonium thiocyanate*, using 2 ml of *ferric ammonium sulphate solution R2* as indicator.

1 ml of 0.1 M *silver nitrate* is equivalent to 36.94 mg of $C_{16}H_{36}IN$.

Tetrachloroethane. $C_2H_2Cl_4$. (M_r 167.9). 1088000. [79-34-5]. 1,1,2,2-Tetrachloroethane.

A clear, colourless liquid, slightly soluble in water, miscible with alcohol.

d_{20}^{20} : about 1.59.

n_D^{20} : about 1.495.

Distillation range (2.2.11). Not less than 95 per cent distils between 145 °C and 147 °C.

Tetrachlorvinphos. $C_{10}H_9Cl_4O_4P$. (M_r 366.0). 1132500. [22248-79-9].

mp: about 95 °C.

A suitable certified reference solution (10 ng/μl in iso-octane) may be used.

Tetracos-15-enoic acid methyl ester. $C_{25}H_{48}O_2$. (M_r 380.7). 1144800. [2733-88-2]. 15-Tetracosanoic acid methyl ester. Methyl tetracos-15-enoate. Nervonic acid methyl ester.

Content: minimum 99.0 per cent of $C_{25}H_{48}O_2$, determined by gas chromatography.

Liquid.

Tetracycline hydrochloride. 1147000.

See *Tetracycline hydrochloride* (0210).

Tetradecane. $C_{14}H_{30}$. (M_r 198.4). 1088200. [629-59-4]. *n*-Tetradecane.

Content: minimum 99.5 per cent *m/m* of $C_{14}H_{30}$.

A colourless liquid.

d_{20}^{20} : about 0.76.

n_D^{20} : about 1.429.

bp: about 252 °C.

mp: about –5 °C.

Tetradecylammonium bromide. $C_{40}H_{84}BrN$. (M_r 659). 1088300. [14937-42-9]. Tetrakis(decyl)ammonium bromide.

A white or slightly coloured, crystalline powder or crystals.

mp: 88 °C to 89 °C.

Tetraethylammonium hydrogen sulphate. $C_8H_{21}NO_4S$. (M_r 227.3). 1116200. [16873-13-5].

Hygroscopic powder.

mp: about 245 °C.

Tetraethylammonium hydroxide solution. $C_8H_{21}NO$. (M_r 147.3). 1100300. [77-98-5].

A 200 g/l aqueous solution, colourless liquid, strongly alkaline.

d_{20}^{20} : about 1.01.

n_D^{20} : about 1.372.

HPLC grade.

Tetraethylene pentamine. $C_8H_{23}N_5$. (M_r 189.3). 1102000. [112-57-2]. 3,6,9-Triazaundecan-1,11-diamine.

Colourless liquid, soluble in acetone.

n_D^{20} : about 1.506.

Storage: protected from humidity and heat.

Tetraheptylammonium bromide. $C_{28}H_{60}BrN$. (M_r 490.7). 1088400. [4368-51-8].

A white or slightly coloured, crystalline powder or crystals. mp: 89 °C to 91 °C.

Tetrahexylammonium bromide. $C_{24}H_{52}BrN$. (M_r 434.6). 1152500. [4328-13-6]. *N,N,N*-Trihexylhexan-1-aminium bromide.

White, crystalline powder, hygroscopic.

mp: about 100 °C.

Tetrahexylammonium hydrogen sulphate.

$C_{24}H_{53}NO_4S$. (M_r 451.8). 1116300. [32503-34-7].

N,N,N-Trihexylhexan-1-aminium hydrogen sulphate.

White crystals.

mp: 100 °C to 102 °C.

Tetrahydrofuran. C_4H_8O . (M_r 72.1). 1088500. [109-99-9]. Tetramethylene oxide.

A clear, colourless, flammable liquid, miscible with water, with alcohol.

d_{20}^{20} : about 0.89.

Do not distil if the tetrahydrofuran does not comply with the test for peroxides.

Peroxides. Place 8 ml of *potassium iodide and starch solution R* in a 12 ml ground-glass-stoppered cylinder about 1.5 cm in diameter. Fill completely with the substance to be examined, shake vigorously and allow to stand protected from light for 30 min. No colour is produced.

Tetrahydrofuran used in spectrophotometry complies with the following additional requirement.

Minimum transmittance (2.2.25), determined using *water R* as compensation liquid: 20 per cent at 255 nm, 80 per cent at 270 nm, 98 per cent at 310 nm.

Tetrahydrofuran for chromatography R. 1147100.

It complies with the requirements of *tetrahydrofuran R* and with the following requirements:

$$d_4^{20} = 0.8892.$$

bp: about 66 °C.

Content: minimum 99.8 per cent of C₄H₈O.

Tetramethylammonium bromide. C₄H₁₂BrN. (*M_r* 154.1). 1156600. [64-20-0]. *N,N,N*-Trimethylmethanaminium bromide.

White or slightly yellow crystals, freely soluble in water.
mp: about 285 °C, with decomposition.

Tetramethylammonium chloride. C₄H₁₂ClN. (*M_r* 109.6). 1100400. [75-57-0].

Colourless crystals, soluble in water and in alcohol.
mp: about 300 °C, with decomposition.

Tetramethylammonium hydrogen sulphate. C₄H₁₃NO₄S. (*M_r* 171.2). 1116400. [80526-82-5].

Hygroscopic powder.

mp: about 295 °C.

Tetramethylammonium hydroxide. C₄H₁₃NO₅H₂O. (*M_r* 181.2). 1122800. [10424-65-4]. Tetramethylammonium hydroxide pentahydrate.

Suitable grade for HPLC.

Tetramethylammonium hydroxide solution. 1088600. [75-59-2].

Content: minimum 10.0 per cent *m/m* of C₄H₁₃NO. (*M_r* 91.2).
A clear, colourless or very pale yellow liquid, miscible with water and with alcohol.

Assay. To 1.000 g add 50 ml of *water R* and titrate with 0.05 *M* sulphuric acid, using 0.1 ml of *methyl red solution R* as indicator.

1 ml of 0.05 *M* sulphuric acid is equivalent to 9.12 mg of C₄H₁₃NO.

Tetramethylammonium hydroxide solution, dilute. 1088601.

Dilute 10 ml of *tetramethylammonium hydroxide solution R* to 100 ml with *aldehyde-free alcohol R*.
Prepare immediately before use.

Tetramethylbenzidine. C₁₆H₂₀N₂. (*M_r* 240.3). 1132600. [54827-17-7]. 3,3',5,5'-Tetramethylbiphenyl-4,4'-diamine.

A powder, practically insoluble in water, very soluble in methanol.

mp: about 169 °C.

1,1,3,3-Tetramethylbutylamine. C₈H₁₉N. (*M_r* 129.3). 1141500. [107-45-9]. 2-Amino-2,4,4-trimethylpentane.

Clear, colourless liquid.

*d*₂₀²⁰: about 0.805.

*n*_D²⁰: about 1.424.

bp: about 140 °C.

Tetramethyldiaminodiphenylmethane. C₁₇H₂₂N₂. (*M_r* 254.4). 1088700. [101-61-1]. 4,4'-Methylenebis(*N,N*-dimethylaniline).

White to bluish-white crystals or leaflets, practically insoluble in water, slightly soluble in alcohol, soluble in mineral acids.
mp: about 90 °C.

Tetramethyldiaminodiphenylmethane reagent. 1088701.

Solution A. Dissolve 2.5 g of *tetramethyldiaminodiphenylmethane R* in 10 ml of *glacial acetic acid R* and add 50 ml of *water R*.

Solution B. Dissolve 5 g of *potassium iodide R* in 100 ml of *water R*.

Solution C. Dissolve 0.30 g of *ninhydrin R* in 10 ml of *glacial acetic acid R* and add 90 ml of *water R*.

Mix solution A, solution B and 1.5 ml of solution C.

Tetramethylethylenediamine. C₆H₁₆N₂. (*M_r* 116.2). 1088800. [110-18-9]. *N,N,N',N'*-Tetramethylethylenediamine.

A colourless liquid, miscible with water and with alcohol.

*d*₂₀²⁰: about 0.78.

*n*_D²⁰: about 1.418.

bp: about 121 °C.

Tetramethylsilane. C₄H₁₂Si. (*M_r* 88.2). 1088900. [75-76-3]. TMS.

A clear, colourless liquid, very slightly soluble in water, soluble in acetone and in alcohol.

*d*₂₀²⁰: about 0.64.

*n*_D²⁰: about 1.358.

bp: about 26 °C.

Tetramethylsilane used in nuclear magnetic resonance spectrometry complies with the following additional requirement.

In the nuclear magnetic resonance spectrum of an approximately 10 per cent *V/V* solution of the tetramethylsilane in *deuterated chloroform R*, the intensity of any foreign signal, excluding those due to spinning side bands and to chloroform, is not greater than the intensity of the C-13 satellite signals located at a distance of 59.1 Hz on each side of the principal signal of tetramethylsilane.

Tetrapropylammonium chloride. C₁₂H₂₈ClN. (*M_r* 221.8). 1151900. [5810-42-4].

White, crystalline powder, sparingly soluble in water.
mp: about 241 °C.

Tetrazolium blue. C₄₀H₃₂Cl₂N₈O₂. (*M_r* 728). 1089000. [1871-22-3]. 3,3'-(3,3'-Dimethoxy[1,1'-biphenyl]-4,4'-diyl)bis[2,5-diphenyl-2*H*-tetrazolium] dichloride.

Yellow crystals, slightly soluble in water, freely soluble in alcohol and in methanol, practically insoluble in acetone.
mp: about 245 °C, with decomposition.

Tetrazolium bromide. C₁₈H₁₆BrN₅S. (*M_r* 414.3). 1152700. [298-93-1]. 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide. MTT.

Thallous sulphate. Tl₂SO₄. (*M_r* 504.8). 1089100. [7446-18-6]. Dithallium sulphate.

White, rhomboid prisms, slightly soluble in water, practically insoluble in alcohol.

Thebaine. C₁₉H₂₁NO₃. (*M_r* 311.4). 1089200. [115-37-7]. (5*R*,9*R*,13*S*)-4,5-Epoxy-3,6-dimethoxy-9a-methylmorphina-6,8-diene.

A white or pale yellow, crystalline powder, very slightly soluble in water, soluble in hot ethanol and in toluene.
mp: about 193 °C.

Chromatography (2.2.27). Examine as prescribed in identification test B in the monograph on *Raw opium (0777)*, applying to the plate as a band (20 mm × 3 mm) 20 µl of a 0.5 g/l solution. The chromatogram obtained shows an orange-red or red principal band with an *R_f* of about 0.5.

Theobromine. 1138800. [83-67-0].

See *Theobromine (0298)*.

Theophylline. 1089300. [58-55-9].

See *Theophylline (0299)*.

Thiamazole. $C_4H_6N_2S$. (M_r 114.2). 1089400. [60-56-0]. Methimazole. 1-Methyl-1*H*-imidazole-2-thiol.

A white or almost white, crystalline powder, freely soluble in water, soluble in alcohol and in methylene chloride.

mp: about 145 °C.

2-(2-Thienyl)acetic acid. $C_6H_6O_2S$. (M_r 142.1). 1089500. [1918-77-0].

A brown powder.

mp: about 65 °C.

Thioacetamide. C_2H_5NS . (M_r 75.1). 1089600. [62-55-5].

A crystalline powder or colourless crystals, freely soluble in water and in alcohol.

mp: about 113 °C.

Thioacetamide reagent. 1089601.

To 0.2 ml of *thioacetamide solution R* add 1 ml of a mixture of 5 ml of *water R*, 15 ml of 1 *M* sodium hydroxide and 20 ml of glycerol (85 per cent) *R*. Heat in a water-bath for 20 s. Prepare immediately before use.

Thioacetamide solution. 1089602.

A 40 g/l solution.

Thiobarbituric acid. $C_4H_4N_2O_2S$. (M_r 144.2). 1111200. [504-17-6]. 4,6-Dihydroxy-2-sulfanylpuridine.

Thiodiethylene glycol. $C_4H_{10}O_2S$. (M_r 122.2). 1122900. [111-48-8]. Di(2-hydroxyethyl) sulphide.

A colourless or yellow, viscous liquid. It contains at least 99.0 per cent of $C_4H_{10}O_2S$.

d_{20}^{20} : about 1.18.

Thioglycollic acid. $C_2H_4O_2S$. (M_r 92.1). 1089700. [68-11-1]. 2-Mercaptoacetic acid.

A colourless liquid, miscible with water, soluble in alcohol.

Thiomersal. $C_9H_9HgNaO_2S$. (M_r 404.8). 1089800. [54-64-8]. Sodium mercuriothiolate. Sodium 2-[(ethylmercurio)thio]benzoate.

A light, yellowish-white, crystalline powder, very soluble in water, freely soluble in alcohol.

Thiourea. CH_4N_2S . (M_r 76.1). 1089900. [62-56-6].

White, crystalline powder or crystals, soluble in water and in alcohol.

mp: about 178 °C.

Threonine. 1090000. [72-19-5].

See *Threonine* (1049).

Thrombin, bovine. 1090200. [9002-04-4].

A preparation of the enzyme, obtained from bovine plasma, that converts fibrinogen into fibrin.

A yellowish-white powder.

Storage: at a temperature below 0 °C.

Thrombin, human. 1090100. [9002-04-4].

Dried human thrombin. A preparation of the enzyme which converts human fibrinogen into fibrin. It is obtained from liquid human plasma and may be prepared by precipitation with suitable salts and organic solvents under controlled conditions of pH, ionic strength and temperature.

A yellowish-white powder, freely soluble in a 9 g/l solution of sodium chloride forming a cloudy, pale yellow solution.

Storage: in a sealed, sterile container under nitrogen, protected from light, at a temperature below 25 °C.

Thrombin solution, human. 1090101.

Reconstitute *human thrombin R* as directed by the manufacturer and dilute with *tris(hydroxymethyl)aminomethane sodium chloride buffer solution pH 7.4 R* to 5 IU/ml.

Thromboplastin. 1090300.

Extract 1.5 g of *acetone-dried ox brain R* with 60 ml of *water R* at 50 °C for 10 min to 15 min, centrifuge at 1500 r/min for 2 min and decant the supernatant liquid. The extract retains its activity for several days when stored in a refrigerator. It may contain 3 g/l of *cresol R* as an antimicrobial preservative.

Thujone. $C_{10}H_{16}O$. (M_r 152.2). 1116500. [546-80-5]. 4-Methyl-1-(1-methylethyl)bicyclo[3.1.0]hexan-3-one.

A colourless or almost colourless liquid, practically insoluble in water, soluble in alcohol and in many other organic solvents.

d_{20}^{20} : about 0.925.

n_D^{20} : about 1.455.

$[\alpha]_D^{20}$: about –15.

bp: about 200 °C.

Thymine. $C_5H_6N_2O_2$. (M_r 126.1). 1090400. [65-71-4]. 5-Methylpyrimidine-2,4(1*H*,3*H*)-dione.

Short needles or plates, slightly soluble in cold water, soluble in hot water. It dissolves in dilute solution of alkali hydroxides.

Thymol. 1090500. [89-83-8]. See *Thymol* (0791).

Thymol used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph *Peppermint oil* (0405).

Test solution. Dissolve 0.1 g in about 10 ml of *acetone R*.

The area of the principal peak is not less than 95.0 per cent of the area of all the peaks in the chromatogram obtained. Disregard the peak due to acetone.

Thymol blue. $C_{27}H_{30}O_5S$. (M_r 466.6). 1090600. [76-61-9]. Thymolsulphonphthalein. 4,4'-(3*H*-2,1-Benzoxathiol-3-ylidene)bis(2-isopropyl-5-methylphenol) *S,S*-dioxide.

A brownish-green to greenish-blue, crystalline powder, slightly soluble in water, soluble in alcohol and in dilute solutions of alkali hydroxides.

Thymol blue solution. 1090601.

Dissolve 0.1 g of *thymol blue R* in a mixture of 2.15 ml of 0.1 *M* sodium hydroxide and 20 ml of *alcohol R* and dilute to 100 ml with *water R*.

Test for sensitivity. To 0.1 ml of the thymol blue solution add 100 ml of *carbon dioxide-free water R* and 0.2 ml of 0.02 *M* sodium hydroxide. The solution is blue. Not more than 0.15 ml of 0.02 *M* hydrochloric acid is required to change the colour to yellow.

Colour change: pH 1.2 (red) to pH 2.8 (yellow); pH 8.0 (olive-green) to pH 9.6 (blue).

Thymolphthalein. $C_{28}H_{30}O_4$. (M_r 430.5). 1090700. [125-20-2]. 3,3-bis(4-Hydroxy-5-isopropyl-2-methylphenyl)-3*H*-isobenzofuran-1-one.

A white or yellowish-white powder, practically insoluble in water, soluble in alcohol and in dilute solutions of alkali hydroxides.

Thymolphthalein solution. 1090701.

A 1 g/l solution in *alcohol R*.

Test for sensitivity. To 0.2 ml of the thymolphthalein solution add 100 ml of *carbon dioxide-free water R*. The solution is colourless. Not more than 0.05 ml of 0.1 M *sodium hydroxide* is required to change the colour to blue.

Colour change: pH 9.3 (colourless) to pH 10.5 (blue).

Tin. Sn. (*A_r* 118.7). 1090800. [7440-31-5].

Silvery-white granules, soluble in hydrochloric acid with release of hydrogen.

Arsenic (2.4.2). 0.1 g complies with limit test A (10 ppm).

Titan yellow. C₂₈H₁₉N₅Na₂O₆S₄. (*M_r* 696). 1090900. [1829-00-1].

Schultz No. 280.

Colour Index No. 19540.

Thiazol yellow. Disodium 2,2'-[(1-triazene-1,3-diyl)di-4,1-phenylene]bis-[6-methylbenzothiazole-7-sulphonate].

A yellowish-brown powder, freely soluble in water and in alcohol.

Titan yellow paper. 1090901.

Immerse strips of filter paper in *titan yellow solution R* and leave for a few minutes. Allow to dry at room temperature.

Titan yellow solution. 1090902.

A 0.5 g/l solution.

Test for sensitivity. To 0.1 ml of the titan yellow solution add 10 ml of *water R*, 0.2 ml of *magnesium standard solution* (10 ppm Mg) *R* and 1.0 ml of 1 M *sodium hydroxide*. A distinct pink colour is visible by comparison with a reference solution prepared in a similar manner omitting the magnesium.

Titanium. Ti. (*A_r* 47.88). 1091000. [7440-32-6].

Content: minimum 99 per cent of Ti.

Metal powder, fine wire (diameter not more than 0.5 mm), sponge.

mp: about 1668 °C.

Density: about 4.507 g/cm³.

Titanium dioxide. 1117900. [13463-67-7].

See *Titanium dioxide* (0150).

Titanium trichloride. TiCl₃. (*M_r* 154.3). 1091200. [7705-07-9]. Titanium(III) chloride.

Reddish-violet crystals, deliquescent, soluble in water and in alcohol.

mp: about 440 °C.

Storage: in an airtight container.

Titanium trichloride solution. 1091201.

*d*₂₀²⁰: about 1.19.

A 150 g/l solution in hydrochloric acid (100 g/l HCl).

Titanium trichloride-sulphuric acid reagent. 1091202.

Carefully mix 20 ml of *titanium trichloride solution R* with 13 ml of *sulphuric acid R*. Add sufficient *strong hydrogen peroxide solution R* to give a yellow colour. Heat until white fumes are evolved. Allow to cool. Dilute with *water R* and repeat the evaporation and addition of *water R* until a colourless solution is obtained. Dilute to 100 ml with *water R*.

TLC octadecylsilyl silica gel plate. 1148600.

Support of glass, metal or plastic coated with a layer of octadecylsilyl silica gel. The plate may contain an organic binder.

TLC octadecylsilyl silica gel F₂₅₄ plate R. 1146600.

Support of glass, metal or plastic coated with a layer of octadecylsilyl silica gel.

It contains a fluorescent indicator having a maximum absorbance in ultraviolet light at 254 nm.

TLC performance test solution. 1116600.

Prepare a mixture of 1.0 ml of each of the following solutions and dilute to 10.0 ml with *acetone R*: a 0.5 g/l solution of *Sudan red G R* in *toluene R*, a 0.5 g/l solution of *methyl orange R* in *ethanol R* prepared immediately before use, a 0.5 g/l solution of *bromocresol green R* in *acetone R* and a 0.25 g/l solution of *methyl red R* in *acetone R*.

TLC silica gel plate. 1116700.

Support of glass, metal or plastic, coated with a layer of silica gel of a suitable thickness and particle size (usually 2 µm to 10 µm for fine particle size (High Performance Thin-Layer Chromatography, HPTLC) plates and 5 µm to 40 µm for normal TLC plates). If necessary, the particle size is indicated after the name of the reagent in the tests where it is used.

The plate may contain an organic binder.

Chromatographic separation. Apply to the plate an appropriate volume (10 µl for a normal TLC plate and 1 µl to 2 µl for a fine particle size plate) of *TLC performance test solution R*. Develop over a pathlength two-thirds of the plate height, using a mixture of 20 volumes of *methanol R* and 80 volumes of *toluene R*. The plate is not satisfactory, unless the chromatogram shows four clearly separated spots, the spot of bromocresol green with an *R_f* value less than 0.15, the spot of methyl orange with an *R_f* value in the range of 0.1 to 0.25, the spot of methyl red with an *R_f* value in the range of 0.35 to 0.55 and the spot of Sudan red G with an *R_f* value in the range of 0.75 to 0.98.

TLC silica gel F₂₅₄ plate. 1116800.

It complies with the requirements prescribed for *TLC silica gel plate R* with the following modification.

It contains a fluorescent indicator having a maximum absorbance at 254 nm.

Fluorescence suppression. Apply separately to the plate at five points increasing volumes (1 µl to 10 µl for normal TLC plates and 0.2 µl to 2 µl for fine particle size plates) of a 1 g/l solution of *benzoic acid R* in a mixture of 15 volumes of *ethanol R* and 85 volumes of *cyclohexane R*. Develop over a pathlength half of the plate height with the same mixture of solvents. After evaporating the solvents examine the chromatogram in ultraviolet light at 254 nm. For normal TLC plates the benzoic acid appears as dark spots on a fluorescent background approximately in the middle of the chromatogram for quantities of 2 µg and greater. For fine particle size plates the benzoic acid appears as dark spots on a fluorescent background approximately in the middle of the chromatogram for quantities of 0.2 µg and greater.

TLC silica gel F₂₅₄, silanised plate. 1117200.

It complies with the requirements prescribed for *TLC silica gel silanised plate R* with the following modification.

It contains a fluorescent indicator having a maximum absorbance at 254 nm.

TLC silica gel G plate. 1116900.

It complies with the requirements prescribed for *TLC silica gel plate R* with the following modification.

It contains calcium sulphate hemihydrate as binder.

TLC silica gel GF₂₅₄ plate. 1117000.

It complies with the requirements prescribed for *TLC silica gel plate R* with the following modifications.

It contains calcium sulphate hemihydrate as binder and a fluorescent indicator having a maximum absorbance at 254 nm.

Fluorescence suppression. Complies with the test prescribed for *TLC silica gel F₂₅₄ plate R*.

TLC silica gel plate for chiral separations, octadecylsilyl. 1137700.

Support of glass, metal or plastic, coated with a layer of octadecylsilyl silica gel, impregnated with Cu²⁺ ions and enantiomerically pure hydroxyproline. The plate may contain an organic binder.

TLC silica gel, silanised plate. 1117100.

Support of glass, metal or plastic, coated with a layer of silanised silica gel of a suitable thickness and particle size (usually 2 µm to 10 µm for fine particle size (High Performance Thin-Layer Chromatography, HPTLC) plates and 5 µm to 40 µm for normal TLC plates). If necessary, the particle size is indicated after the name of the reagent in the tests where it is used.

The plate may contain an organic binder.

Chromatographic separation. Introduce 0.1 g each of *methyl laurate R*, *methyl myristate R*, *methyl palmitate R* and *methyl stearate R* into a 250 ml conical flask. Add 40 ml of *alcoholic potassium hydroxide solution R* and heat under a reflux condenser on a water-bath for 1 h. Allow to cool, transfer the solution to a separating funnel by means of 100 ml of *water R*, acidify (pH 2 to 3) with *dilute hydrochloric acid R* and shake with three quantities each of 10 ml of *methylene chloride R*. Dry the combined methylene chloride extracts over *anhydrous sodium sulphate R*, filter and evaporate to dryness on a water-bath. Dissolve the residue in 50 ml of *methylene chloride R*. Examine by thin-layer chromatography (2.2.27), using *silanised TLC silica gel plate R*. Apply an appropriate quantity (about 10 µl for normal TLC plates and about 1 µl to 2 µl for fine particle size plates) of the methylene chloride solution at each of three separate points. Develop over a pathlength two-thirds of the plate height with a mixture of 10 volumes of *glacial acetic acid R*, 25 volumes of *water R* and 65 volumes of *dioxan R*. Dry the plate at 120 °C for 30 min. Allow to cool, spray with a 35 g/l solution of *phosphomolybdic acid R* in *2-propanol R* and heat at 150 °C until the spots become visible. Treat the plate with ammonia vapour until the background is white. The chromatograms show four clearly separated, well-defined spots.

α-Tocopherol. 1152300. [10191-41-0].

See *all-rac-α-Tocopherol (0692)*.

α-Tocopheryl acetate. 1152400. [7695-91-2].

See *all-rac-α-Tocopheryl acetate (0439)*.

o-Tolidine. C₁₄H₁₆N₂. (M_r 212.3). 1123000. [119-93-7]. 3,3'-Dimethylbenzidine.

Content: minimum 97.0 per cent of C₁₄H₁₆N₂.

A light brownish, crystalline power.

mp: about 130 °C.

o-Tolidine solution. 1123001.

Dissolve 0.16 g of *o-tolidine R* in 30.0 ml of *glacial acetic acid R*, add 1.0 g of *potassium iodide R* and dilute to 500.0 ml with *water R*.

Toluene. C₇H₈. (M_r 92.1). 1091300. [108-88-3]. Methylbenzene.

A clear, colourless, flammable liquid, very slightly soluble in water, miscible with alcohol.

*d*₂₀²⁰: 0.865 to 0.870.

bp: about 110 °C.

Toluene, sulphur-free. 1091301.

Complies with the requirements prescribed for *toluene R* and with the following additional requirements:

Sulphur compounds. To 10 ml add 1 ml of *ethanol R* and 3 ml of *potassium plumbite solution R* and boil under a reflux condenser for 15 min. Allow to stand for 5 min. No darkening is produced in the aqueous layer.

Thiophen-related substances. Shake 2 ml with 5 ml of *isatin reagent R* for 5 min and allow to stand for 15 min. No blue colour is produced in the lower layer.

Toluenesulphonamide. C₇H₉NO₂S. (M_r 171.2). 1091500. [70-55-3]. 4-Methylbenzenesulphonamide. *p*-Toluenesulphonamide.

A white, crystalline powder, slightly soluble in water, soluble in alcohol and in solutions of alkali hydroxides.

mp: about 136 °C.

Chromatography. Examine as prescribed in the monograph on *Tolbutamide (0304)*; the chromatogram shows only one principal spot.

o-Toluenesulphonamide. C₇H₉NO₂S. (M_r 171.2). 1091400. [88-19-7]. 2-Methylbenzenesulphonamide.

A white, crystalline powder, slightly soluble in water, soluble in alcohol and in solutions of alkali hydroxides.

mp: about 156 °C.

p-Toluenesulphonamide. 1091500. [70-55-3]. See *toluenesulphonamide R*.

Toluenesulphonic acid. C₇H₉O₃S.H₂O. (M_r 190.2). 1091600. [6192-52-5]. 4-Methylbenzenesulphonic acid.

Content: minimum 87.0 per cent of C₇H₈O₃S.

A white, crystalline powder or crystals, freely soluble in water, soluble in alcohol.

o-Toluidine. C₇H₉N. (M_r 107.2). 1091700. [95-53-4]. 2-Methylaniline.

A pale-yellow liquid becoming reddish-brown on exposure to air and light, slightly soluble in water, soluble in alcohol and in dilute acids.

*d*₂₀²⁰: about 1.01.

*n*_D²⁰: about 1.569.

bp: about 200 °C.

Storage: in an airtight container, protected from light.

o-Toluidine hydrochloride. C₇H₁₀ClN. (M_r 143.6). 1117300. [636-21-5]. 2-Methylaniline hydrochloride. 2-Methylbenzenamine hydrochloride.

Content: minimum 98.0 per cent of C₇H₁₀ClN.

mp: 215 °C to 217 °C.

p-Toluidine. C₇H₉N. (M_r 107.2). 1091800. [106-49-0]. 4-Methylaniline.

Lustrous plates or flakes, slightly soluble in water, freely soluble in acetone and in alcohol.

mp: about 44 °C.

Toluidine blue. C₁₅H₁₆ClN₃S. (M_r 305.8). 1091900. [92-31-9]. Schultz No. 1041.

Colour Index No. 52040.

Toluidine Blue O. 3-Amino-7-dimethylamino-2-methylphenothiazin-5-ium chloride.

A dark-green powder, soluble in water, slightly soluble in alcohol.

Tosylarginine methyl ester hydrochloride.C₁₄H₂₃ClN₄O₄S. (*M_r* 378.9). 1092000. [1784-03-8].*N*-Tosyl-L-arginine methyl ester hydrochloride. Methyl (S)-5-guanidino-2-(4-methylbenzenesulphonamido)valerate hydrochloride.[α]_D²⁰: −12 to −16, determined on a 40 g/l solution.

mp: about 145 °C.

Tosylarginine methyl ester hydrochloride solution.
1092001.To 98.5 mg of *tosylarginine methyl ester hydrochloride R* add 5 ml of *tris(hydroxymethyl)aminomethane buffer solution pH 8.1 R* and shake to dissolve. Add 2.5 ml of *methyl red mixed solution R* and dilute to 25.0 ml with *water R*.**Tosyl-lysyl-chloromethane hydrochloride.**C₁₄H₂₂Cl₂N₂O₃S. (*M_r* 369.3). 1092100. [4238-41-9].*N*-Tosyl-L-lysyl-chloromethane hydrochloride. (3S)-7-Amino-1-chloro-3-(4-methylbenzenesulphonamido)heptan-2-one hydrochloride.[α]_D²⁰: −7 to −9, determined on a 20 g/l solution.

mp: about 155 °C, with decomposition.

A_{1 cm}^{1%}: 310 to 340, determined at 230 nm in *water R*.**Tosylphenylalanylchloromethane.** C₁₇H₁₈ClNO₃S. (*M_r* 351.9). 1092200. [402-71-1]. *N*-Tosyl-L-phenylalanylchloromethane.[α]_D²⁰: −85 to −89, determined on a 10 g/l solution in *alcohol R*.

mp: about 105 °C.

A_{1 cm}^{1%}: 290 to 320, determined at 228.5 nm in *alcohol R*.**Toxaphene.** 1132800. [8001-35-2].

A mixture of polychloro derivatives.

mp: 65 °C to 90 °C.

A suitable certified reference solution (10 ng/μl in iso-octane) may be used.

Tragacanth. 1092300. [9000-65-1].See *Tragacanth (0532)*.**Triacetin.** C₉H₁₄O₆. (*M_r* 218.2). 1092400. [102-76-1].

Propane-1,2,3-triyl triacetate.

An almost clear, colourless to yellowish liquid, soluble in water, miscible with alcohol.

*d*₂₀²⁰: about 1.16.*n*_D²⁰: about 1.43.

bp: about 260 °C.

Triamcinolone. C₂₁H₂₇FO₆. (*M_r* 394.4). 1111300. [124-94-7].

9-Fluoro-11β,16α,17,21-tetrahydroxypregna-1,4-diene-3,20-dione.

A crystalline powder.

mp: 262 °C to 263 °C.

Triamcinolone acetonide. 1133100. [76-25-5].See *Triamcinolone acetonide (0533)*.**Tributyl citrate.** C₁₈H₃₂O₇. (*M_r* 360.4). 1152800. [77-94-1].

Tributyl 2-hydroxypropane-1,2,3-tricarboxylate.

*d*₄²⁰: about 1.043.*n*_D²⁰: about 1.445.**Trichlorethylene.** 1102100.See *Trichloroethylene R*.**Trichloroacetic acid.** C₂HCl₃O₂. (*M_r* 163.4). 1092500. [76-03-9].

Colourless crystals or a crystalline mass, very deliquescent, very soluble in water and in alcohol.

Storage: in an airtight container.**Trichloroacetic acid solution.** 1092501.Dissolve 40.0 g of *trichloroacetic acid R* in *water R* and dilute to 1000.0 ml with the same solvent. Verify the concentration by titration with 0.1 M *sodium hydroxide* and adjust if necessary to 40 ± 1 g/l.**1,1,1-Trichloroethane.** C₂H₃Cl₃. (*M_r* 133.4). 1092600. [71-55-6]. Methylchloroform.

A non-flammable liquid, practically insoluble in water, soluble in acetone and in methanol.

*d*₂₀²⁰: about 1.34.*n*_D²⁰: about 1.438.

bp: about 74 °C.

Trichloroethylene. C₂HCl₃. (*M_r* 131.4). 1102100. [79-01-6].

A colourless liquid, practically insoluble in water, miscible with alcohol.

*d*₂₀²⁰: about 1.46.*n*_D²⁰: about 1.477.**Trichlorotrifluoroethane.** C₂Cl₃F₃. (*M_r* 187.4). 1092700. [76-13-1]. 1,1,2-Trichloro-1,2,2-trifluoroethane.

A colourless, volatile liquid, practically insoluble in water, miscible with acetone.

*d*₂₀²⁰: about 1.58.*Distillation range (2.2.11)*. Not less than 98 per cent distils between 47 °C and 48 °C.**Tricine.** C₆H₁₃NO₅. (*M_r* 179.2). 1138900. [5704-04-1]. *N*-[2-Hydroxy-1,1-bis(hydroxymethyl)ethyl]glycine.

Use electrophoresis-grade reagent.

mp: about 183 °C.

Tricosane. C₂₃H₄₈. (*M_r* 324.6). 1092800. [638-67-5].

White crystals, practically insoluble in water, soluble in hexane.

*n*_D²⁰: about 1.447.

mp: about 48 °C.

Tridocosahexaenoin. C₆₉H₉₈O₆. (*M_r* 1023.5). 1144900. [124596-98-1]. Triglyceride of docosahexaenoic acid(C22:6). Glycerol tridocosahexaenoate. Propane-1,2,3-triyl tri-(*all-Z*)-docosa-4,7,10,13,16,19-hexaenoate.

The reagent from Nu-Chek Prep, Inc. has been found suitable.

Triethanolamine. 1092900. [102-71-6].See *Trolamine (1577)*.**Triethylamine.** C₆H₁₅N. (*M_r* 101.2). 1093000. [121-44-8]. *N,N*-Diethylethanamine.

A colourless liquid, slightly soluble in water at a temperature below 18.7 °C, miscible with alcohol.

*d*₂₀²⁰: about 0.727.*n*_D²⁰: about 1.401.

bp: about 90 °C.

Triethylenediamine. $C_6H_{12}N_2$. (M_r 112.2). 1093100. 1,4-Diazabicyclo[2.2.2]octane.

Crystals, very hygroscopic, sublimes readily at room temperature, freely soluble in water, in acetone and in ethanol.

bp: about 174 °C.

mp: about 158 °C.

Storage: in an airtight container.

Triethyl phosphonoformate. $C_7H_{15}O_5P$. (M_r 210.2). 1132900. [1474-78-8]. Ethyl (diethoxyphosphoryl)formate.

Colourless liquid.

bp_{12 mm}: about 135 °C.

Trifluoroacetic acid. $C_2HF_3O_2$. (M_r 114.0). 1093200. [76-05-1].

Content: minimum 99 per cent of $C_2HF_3O_2$.

Liquid, miscible with acetone and with alcohol.

d_{20}^{20} : about 1.53.

bp: about 72 °C.

Use a grade suitable for protein sequencing.

Storage: in an airtight container.

Trifluoroacetic anhydride. $C_4F_6O_3$. (M_r 210.0). 1093300. [407-25-0].

Colourless liquid.

d_{20}^{20} : about 1.5.

Trigonelline hydrochloride. $C_7H_8ClNO_2$. (M_r 173.6). 1117400. [6138-41-6]. 3-Carboxy-1-methylpyridinium chloride. Nicotinic acid *N*-methylbetaine hydrochloride.

A crystalline powder, very soluble in water, soluble in alcohol.

mp: about 258 °C.

Trimethylpentane. C_8H_{18} . (M_r 114.2). 1093400. [540-84-1]. Iso-octane. 2,2,4-Trimethylpentane.

A colourless, flammable liquid, practically insoluble in water, soluble in ethanol.

d_{20}^{20} : 0.691 to 0.696.

n_D^{20} : 1.391 to 1.393.

Distillation range (2.2.11). Not less than 95 per cent distils between 98 °C and 100 °C.

Trimethylpentane used in spectrophotometry complies with the following additional requirement.

Minimum transmittance (2.2.25), determined using *water R* as compensation liquid: 98 per cent from 250 nm to 420 nm.

Trimethylpentane R1. 1093401.

Complies with the requirements prescribed for *trimethylpentane R* with the following modification.

Absorbance (2.2.25). Not more than 0.07 from 220 nm to 360 nm, determined using *water R* as the compensation liquid.

***N,O*-bis(Trimethylsilyl)acetamide.** $C_8H_{21}NOSi_2$. (M_r 203.4). 1093600. [10416-59-8].

Colourless liquid.

d_{20}^{20} : about 0.83.

***N*-Trimethylsilylimidazole.** $C_6H_{12}N_2Si$. (M_r 140.3). 1100500. [18156-74-6]. 1-Trimethylsilylimidazole.

A colourless, hygroscopic liquid.

d_{20}^{20} : about 0.96.

n_D^{20} : about 1.48.

Storage: in an airtight container.

***N,O*-bis(Trimethylsilyl)trifluoroacetamide.** $C_8H_{18}F_3NOSi_2$. (M_r 257.4). 1133200. [25561-30-2]. BSTFA.

Colourless liquid.

d_{20}^{20} : about 0.97.

n_D^{20} : about 1.38.

bp_{12 mm}: about 40 °C

Trimethylsulphonium hydroxide. $C_3H_{10}OS$. (M_r 94.2). 1145000. [17287-03-5].

d_4^{20} : about 0.81.

2,4,6-Trinitrobenzene sulphonic acid. $C_6H_3N_3O_9S \cdot 3H_2O$. (M_r 347.2). 1117500. [2508-19-2].

A white, crystalline powder, soluble in water.

mp: 190 °C to 195 °C.

Triphenylmethanol. $C_{19}H_{16}O$. (M_r 260.3). 1093700. [76-84-6]. Triphenylcarbinol.

Colourless crystals, practically insoluble in water, freely soluble in alcohol.

Triphenyltetrazolium chloride. $C_{19}H_{15}ClN_4$. (M_r 334.8). 1093800. [298-96-4]. 2,3,5-Triphenyl-2*H*-tetrazolium chloride.

Content: minimum 98.0 per cent of $C_{19}H_{15}ClN_4$. A pale or dull-yellow powder, soluble in water, in acetone and in alcohol.

mp: about 240 °C, with decomposition.

Assay. Dissolve 1.000 g in a mixture of 5 ml of *dilute nitric acid R* and 45 ml of *water R*. Add 50.0 ml of 0.1 *M silver nitrate* and heat to boiling. Allow to cool, add 3 ml of *dibutyl phthalate R*, shake vigorously and titrate with 0.1 *M ammonium thiocyanate*, using 2 ml of *ferric ammonium sulphate solution R2* as indicator.

1 ml of 0.1 *M silver nitrate* is equivalent to 33.48 mg of $C_{19}H_{15}ClN_4$.

Storage: protected from light.

Triphenyltetrazolium chloride solution. 1093801.

A 5 g/l solution in *aldehyde-free alcohol R*.

Storage: protected from light.

Triscyanoethoxypropane. $C_{12}H_{17}N_3O_3$. (M_r 251.3). 1093900. 1,2,3-Tris(2-cyanoethoxy)propane.

A viscous, brown-yellow liquid, soluble in methanol. Used as a stationary phase in gas chromatography.

d_{20}^{20} : about 1.11.

Viscosity (2.2.9): about 172 mPas.

1,3,5-Tris[3,5-di(1,1-dimethylethyl)-4-hydroxybenzyl]-1,3,5-triazine-2,4,6(1*H*,3*H*,5*H*)-trione. $C_{48}H_{69}O_6N_3$. (M_r 784.1). 1094000. [27676-62-6].

A white, crystalline powder.

mp: 218 °C to 222 °C.

Tris[2,4-di(1,1-dimethylethyl)phenyl] phosphite. $C_{42}H_{63}O_3P$. (M_r 647). 1094100. [31570-04-4].

White powder.

mp: 182 °C to 186 °C.

Tris(hydroxymethyl)aminomethane. 1094200. [77-86-1]. See *Trometamol* (1053).

Tris(hydroxymethyl)aminomethane solution. 1094201.

A solution containing the equivalent of 24.22 g of $C_4H_{11}NO_3$ in 1000.0 ml.

Tris(hydroxymethyl)aminomethane solution R1. 1094202.

Dissolve 60.6 mg of *tris(hydroxymethyl)aminomethane R* and 0.234 g of *sodium chloride R* in *water R* and dilute to 100 ml with the same solvent.

Storage: at 2 °C to 8 °C; use within 3 days.

Tripotassium phosphate trihydrate. $K_3PO_4 \cdot 3H_2O$. (M_r 266.3). 1155300. [22763-03-7].

White or almost white crystalline powder, freely soluble in water.

Trisodium phosphate dodecahydrate. $Na_3PO_4 \cdot 12H_2O$. (M_r 380.1). 1094300. [10101-89-0].

Colourless or white crystals, freely soluble in water.

Trypsin. 1094500. [9002-07-7].

A proteolytic enzyme obtained by activation of trypsinogen extracted from the pancreas of beef (*Bos taurus* L.).

A white, crystalline or amorphous powder, sparingly soluble in water.

Trypsin for peptide mapping. 1094600. [9002-07-7].

Trypsin of high purity treated to eliminate chymotryptic activity.

Tryptophan. $C_{11}H_{12}N_2O_2$. (M_r 204.2). 1094700. [73-22-3].

A white or yellowish-white, crystalline powder or colourless crystals, slightly soluble in water, very slightly soluble in alcohol.

$[\alpha]_D^{20}$: about –30, determined on a 10 g/l solution.

Tyramine. $C_8H_{11}NO$. (M_r 137.2). 1117600. [51-67-2]. 4-(2-Aminoethyl)phenol.

Crystals, sparingly soluble in water, soluble in boiling ethanol.

mp: 164 °C to 165 °C.

Tyrosine. $C_9H_{11}NO_3$. (M_r 181.2). 1094800. [60-18-4]. 2-Amino-3-(4-hydroxyphenyl)propionic acid.

A white, crystalline powder or colourless or white crystals, slightly soluble in water, practically insoluble in acetone and in ethanol, soluble in dilute hydrochloric acid and in solutions of alkali hydroxides.

Chromatography. Examine as prescribed in the monograph on *Levodopa* (0038); the chromatogram shows only one principal spot.

Umbelliferone. $C_9H_6O_3$. (M_r 162.1). 1137500. [93-35-6]. 7-Hydroxycoumarin. 7-Hydroxy-2H-1-benzopyran-2-one.

Needles from water.

mp: 225 °C to 228 °C.

Urea. 1095000. [57-13-6].

See *Urea* (0743).

Uridine. $C_9H_{12}N_2O_6$. (M_r 244.2). 1095100. [58-96-8]. 1-β-D-Ribofuranosyluracil.

A white or almost white, crystalline powder, soluble in water.

mp: about 165 °C.

Ursolic acid. $C_{30}H_{48}O_3$. (M_r 456.7). 1141600. [77-52-1]. (3β)-3-Hydroxyurs-12-en-28-oic acid.

White powder, practically insoluble in water, sparingly soluble in methanol, slightly soluble in alcohol.

$[\alpha]_D^{21}$: about 67.50 (10 g/l solution in a 56.1 g/l solution of *potassium hydroxide R* in *alcohol R*).

mp: 285 °C to 288 °C.

Valencene. $C_{15}H_{24}$. (M_r 204.4). 1152100.

[4630-07-3]. 4βH,5α-Eremophila-1(10),11-diene.

(1R,7R,8aS)-1,8a-Dimethyl-7-(1-methylethenyl)-1,2,3,5,6,7,8,8a-octahydronaphthalene.

Oily, colourless to pale yellow liquid, with a characteristic odour, practically insoluble in water, soluble in alcohol.

d_4^{20} : about 0.918.

n_D^{20} : about 1.508.

bp: about 123 °C.

Valencene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Sweet orange oil* (1811).

The content is not less than 90 per cent, calculated by the normalisation procedure.

Valeric acid. $C_5H_{10}O_2$. (M_r 102.1). 1095200. [109-52-4]. Pentanoic acid.

A colourless liquid, soluble in water, freely soluble in alcohol.

d_{20}^{20} : about 0.94.

n_D^{20} : about 1.409.

bp: about 186 °C.

Vanillin. 1095300. [121-33-5].

See *Vanillin* (0747).

Vanillin reagent. 1095301.

Carefully add, dropwise, 2 ml of *sulphuric acid R* to 100 ml of a 10 g/l solution of *vanillin R* in *alcohol R*.

Storage: use within 48 h.

Vanillin solution, phosphoric. 1095302.

Dissolve 1.0 g of *vanillin R* in 25 ml of *alcohol R*. Add 25 ml of *water R* and 35 ml of *phosphoric acid R*.

Verbenone. $C_{10}H_{14}O$. (M_r 150.2). 1140500. [1196-01-6]. (1S,5S)-4,6,6-Trimethylbicyclo[3.1.1]hept-3-en-2-one.

Oil with a characteristic odour, practically insoluble in water, miscible with organic solvents.

d_{20}^{20} : about 0.978.

n_D^{18} : about 1.49.

$[\alpha]_D^{18}$: about +249.6.

bp: 227 °C to 228 °C.

mp: about 6.5 °C.

Verbenone used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Rosemary oil* (1846).

The content is not less than 99 per cent, calculated by the normalisation procedure.

Vinyl acetate. $C_4H_6O_2$. (M_r 86.10). 1111800. [108-05-4]. Ethenyl acetate.

d_{20}^{20} : about 0.930.

bp: about 72 °C.

Vinyl chloride. C_2H_3Cl . (M_r 62.5). 1095400. [75-01-4].

A colourless gas, slightly soluble in organic solvents.

Vinyl polymer for chromatography, octadecyl. 1155400.

Spherical particles (5 µm) of a vinyl alcohol copolymer chemically modified by bonding of octadecyl groups on the hydroxyl groups.

Vinyl polymer for chromatography, octadecylsilyl. 1121600.

Spherical particles (5 µm) of a vinyl alcohol copolymer bonded to an octadecylsilane. Carbon content of 17 per cent.

2-Vinylpyridine. C₇H₇N. (*M_r* 105.1). 1102200. [100-69-6].

A yellow liquid, miscible in water.

*d*₂₀²⁰: about 0.97.

*n*_D²⁰: about 1.549.

1-Vinylpyrrolidin-2-one. C₆H₉NO. (*M_r* 111.1). 1111900. [88-12-0]. 1-Ethenylpyrrolidin-2-one.

Content: minimum 99.0 per cent of C₆H₉NO.

A clear colourless liquid.

Water (2.5.12): maximum 0.1 per cent, determined on 2.5 g. Use as the solvent, a mixture of 50 ml of *anhydrous methanol R* and 10 ml of *butyrolactone R*.

Assay. Examine by gas chromatography (2.2.28).

The chromatography may be carried out using

- a fused-silica column 30 m long and 0.5 mm in internal diameter the inner wall of which is coated with a 1.0 µm layer of *macrogol 20 000 R*,
- *helium for chromatography R* as the carrier gas,
- a flame-ionisation detector,

maintaining the temperature of the injection port at 190 °C and programming the temperature of the column as follows: maintain the temperature at 80 °C for 1 min and then increase it to 190 °C at a rate of 10 °C per minute. Maintain at 190 °C for 15 min. Inject 0.3 µl of the substance to be examined and adjust the flow rate of the carrier gas so that the retention time of the peak corresponding to 1-vinylpyrrolidin-2-one is about 17 min. Determine the content of C₆H₉NO by internal normalisation.

Vitexin. C₂₁H₂₀O₁₀. (*M_r* 448.4). 1133300. [3681-93-4]. Apigenin 8-glucoside.

Yellow powder.

Storage: in an airtight container, protected from light.

Water. 1095500. [7732-18-5].

See *Purified water* (0008).

Water R1. 1095508.

Prepared from *distilled water R* by multiple distillation. Remove carbon dioxide by boiling for at least 15 min before use in a boiling flask of fused silica or borosilicate glass and cool. Any other suitable method may be used. The boiling flask has been already used for the test or has been filled with *water R* and kept in an autoclave at 121 °C for at least 1 h prior to first use. When tested immediately before use, *water R1* is neutral to *methyl red solution R*, i.e. it shall produce an orange-red (not a violet-red or yellow) colour corresponding to pH 5.5 ± 0.1 when 0.05 ml of *methyl red solution R* is added to 50 ml of the water to be examined.

Conductivity: maximum 1 µS·cm⁻¹, determined at 25 °C by an in-line conductivity meter (see *Purified water* (0008)).

Water, ammonium-free. 1095501. [7732-18-5].

To 100 ml of *water R* add 0.1 ml of *sulphuric acid R*. Distil using the apparatus described for the determination of *Distillation range* (2.2.11). Reject the first 10 ml and collect the following 50 ml.

Water, carbon dioxide-free. 1095502. [7732-18-5].

Water R which has been boiled for a few minutes and protected from the atmosphere during cooling and storage.

Water for chromatography. 1095503. [7732-18-5].

Deionised *water R* with a resistivity of not less than 0.18 Mohm·m.

Water, distilled. 1095504. [7732-18-5].

Water R prepared by distillation.

Water, distilled, deionised. 1095508.

Deionised *water R* prepared by distillation with a resistivity of not less than 18 Mohm·m.

Water for injections. 1095505. [7732-18-5].

See *Water for injections* (0169).

Water, nitrate-free. 1095506. [7732-18-5].

To 100 ml of *water R* add a few milligrams of *potassium permanganate R* and of *barium hydroxide R*. Distil using the apparatus described for the determination of *Distillation range* (2.2.11). Reject the first 10 ml and collect the following 50 ml.

Water, particle-free. 1095507. [7732-18-5].

Filter *water R* through a membrane with a pore size of 0.22 µm.

Weak cationic resin. 1096000.

Polymethacrylic resin, slightly acid, with carboxyl groups present in a protonated form.

Particle size: 75 µm to 160 µm.

pH limits of use: 5 to 14.

Maximum temperature of use: 120 °C.

Xanthydrol. C₁₃H₁₀O₂. (*M_r* 198.2). 1096100. [90-46-0]. 9-Xanthanol.

Content: minimum 90.0 per cent of C₁₃H₁₀O₂.

A white to pale-yellow powder, very slightly soluble in water, soluble in alcohol and in glacial acetic acid.

It is also available as a methanolic solution containing 90 g/l to 110 g/l of xanthydrol.

mp: about 123 °C.

Assay. In a 250 ml flask dissolve 0.300 g in 3 ml of *methanol R* or use 3.0 ml of solution. Add 50 ml of *glacial acetic acid R* and, dropwise with shaking, 25 ml of a 20 g/l solution of *urea R*. Allow to stand for 12 h, collect the precipitate on a sintered-glass filter (16), wash with 20 ml of *alcohol R*, dry in an oven at 100 °C to 105 °C and weigh. 1 g of precipitate is equivalent to 0.9429 g of xanthydrol.

Storage: protected from light. If a methanolic solution is used, store in small sealed ampoules and filter before use if necessary.

Xanthydrol R1. 1096101.

Complies with the requirements prescribed for *xanthydrol R* and with the following requirement.

Content: minimum 98.0 per cent of C₁₃H₁₀O₂.

Xanthydrol solution. 1096102.

To 0.1 ml of a 100 g/l solution of *xanthydrol R* in *methanol R* add 100 ml of *anhydrous acetic acid R* and 1 ml of *hydrochloric acid R*. Allow to stand for 24 h before using.

Xylene. C₈H₁₀. (*M_r* 106.2). 1096200. [1330-20-7].

Mixture of isomers. A clear, colourless, flammable liquid, practically insoluble in water, miscible with alcohol.

d_{20}^{20} : about 0.867.

n_D^{20} : about 1.497.

bp: about 138 °C.

m-Xylene. C_8H_{10} . (M_r 106.2). 1117700. [108-38-3].
1,3-Dimethylbenzene.

A clear, colourless, flammable liquid, practically insoluble in water, miscible with alcohol.

d_{20}^{20} : about 0.884.

n_D^{20} : about 1.497.

bp: about 139 °C.

mp: about -47 °C.

o-Xylene. C_8H_{10} . (M_r 106.2). 1100600. [95-47-6].
1,2-Dimethylbenzene.

A clear, colourless, flammable liquid, practically insoluble in water, miscible with alcohol.

d_{20}^{20} : about 0.881.

n_D^{20} : about 1.505.

bp: about 144 °C.

mp: about -25 °C.

Xylenol orange. $C_{31}H_{28}N_2Na_4O_{13}S$. (M_r 761). 1096300. [3618-43-7]. Tetrasodium 3,3'-(3H-2,1-benzoxathiol-3-ylidene)bis[(6-hydroxy-5-methyl-3,1-phenylene)methyleneiminobisacetate] S,S-dioxide.

A reddish-brown crystalline powder, soluble in water.

Xylenol orange triturate. 1096301.

Triturate 1 part of *xylenol orange R* with 99 parts of *potassium nitrate R*.

Test for sensitivity. To 50 ml of *water R* add 1 ml of *dilute acetic acid R*, 50 mg of the xylenol orange triturate and 0.05 ml of *lead nitrate solution R*. Add *hexamethylenetetramine R* until the colour changes from yellow to violet-red. After addition of 0.1 ml of *0.1 M sodium edetate* the colour changes to yellow.

Xylose. 1096400. [58-86-6].

See *Xylose* (1278).

Zinc. Zn. (A_r 65.4). 1096500. [7440-66-6].

Content: minimum 99.5 per cent of Zn.

Silver-white cylinders, granules, pellets or filings with a blue sheen.

Arsenic (2.4.2). 5.0 g complies with limit test A (0.2 ppm). Dissolve in a mixture of the 15 ml of *hydrochloric acid R* and 25 ml of *water R* prescribed.

Zinc, activated. 1096501.

Place the zinc cylinders or pellets to be activated in a conical flask and add a sufficient quantity of a 50 ppm solution of *chloroplatinic acid R* to cover the metal. Allow the metal to remain in contact with the solution for 10 min, wash, drain and dry immediately.

Arsenic. To 5 g of the activated zinc add 15 ml of *hydrochloric acid R*, 25 ml of *water R*, 0.1 ml of *stannous chloride solution R* and 5 ml of *potassium iodide solution R*. Treat as described in limit test A for arsenic (2.4.2). No stain is produced on the *mercuric bromide paper R*.

Activity. Repeat the test for arsenic using the same reagents and adding a solution containing 1 µg of arsenic. An appreciable stain appears on the *mercuric bromide paper R*.

Zinc acetate. $(C_2H_3O_2)_2Zn \cdot 2H_2O$. (M_r 219.5). 1102300. [5970-45-6]. Zinc acetate dihydrate.

Bright white crystals, slightly efflorescent, freely soluble in water, soluble in alcohol. It loses its crystallisation water at 100 °C.

d_{20}^{20} : about 1.735.

mp: about 237 °C.

Zinc acetate solution. 1102301.

Mix 600 ml of *water R* with 150 ml of *glacial acetic acid R*, 54.9 g of *zinc acetate R* and stir to dissolve. Continue stirring while adding 150 ml of *concentrated ammonia R*. Cool to room temperature and adjust with *ammonia R* to pH 6.4. Dilute the mixture to 1 litre with *water R*.

Zinc chloride. 1096600. [7646-85-7].

See *Zinc chloride* (0110).

Zinc chloride-formic acid solution. 1096601.

Dissolve 20 g of *zinc chloride R* in 80 g of an 850 g/l solution of *anhydrous formic acid R*.

Zinc chloride solution, iodinated. 1096602.

Dissolve 20 g of *zinc chloride R* and 6.5 g of *potassium iodide R* in 10.5 ml of *water R*. Add 0.5 g of *iodine R* and shake for 15 min. Filter if necessary.

Storage: protected from light.

Zinc iodide and starch solution. 1096502.

To a solution of 2 g of *zinc chloride R* in 10 ml of *water R* add 0.4 g of *soluble starch R* and heat until the starch has dissolved. After cooling to room temperature add 1.0 ml of a colourless solution containing 0.10 g *zinc R* as filings and 0.2 g of *iodine R* in *water R*. Dilute the solution to 100 ml with *water R* and filter.

Storage: protected from light.

Test for sensitivity. Dilute 0.05 ml of *sodium nitrite solution R* to 50 ml with *water R*. To 5 ml of this solution add 0.1 ml of *dilute sulphuric acid R* and 0.05 ml of the zinc iodide and starch solution and mix. The solution becomes blue.

Zinc oxide. 1096700. [1314-13-2].

See *Zinc oxide* (0252).

Zinc powder. Zn. (A_r 65.4). 1096800. [7440-66-6].

Content: minimum 90.0 per cent of Zn (A_r 65.4).

A very fine, grey powder, soluble in *dilute hydrochloric acid R*.

Zinc sulphate. 1097000. [7446-20-0].

See *Zinc sulphate* (0111).

Zirconyl chloride. A basic salt corresponding approximately to the formula $ZrCl_2O \cdot 8H_2O$. 1097100. [15461-27-5].

Content: minimum 96.0 per cent of $ZrCl_2O \cdot 8H_2O$.

White or almost white, crystalline powder or crystals, freely soluble in water and in alcohol.

Assay. Dissolve 0.600 g in a mixture of 5 ml of *nitric acid R* and 50 ml of *water R*. Add 50.0 ml of *0.1 M silver nitrate* and 3 ml of *dibutyl phthalate R* and shake. Using 2 ml of *ferric ammonium sulphate solution R2* as indicator, titrate with *0.1 M ammonium thiocyanate* until a reddish-yellow colour is obtained.

1 ml of *0.1 M silver nitrate* is equivalent to 16.11 mg of $ZrCl_2O \cdot 8H_2O$.

Zirconyl nitrate. A basic salt corresponding approximately to the formula $\text{ZrO}(\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$. 1097200. [14985-18-3].

A white powder or crystals, hygroscopic, soluble in water. The aqueous solution is a clear or at most slightly opalescent liquid.

Storage: in an airtight container.

Zirconyl nitrate solution. 1097201.

A 1 g/l solution in a mixture of 40 ml of *water R* and 60 ml of *hydrochloric acid R*.

01/2005:40102

4.1.2. STANDARD SOLUTIONS FOR LIMIT TESTS

Acetaldehyde standard solution (100 ppm $\text{C}_2\text{H}_4\text{O}$). 5000100.

Dissolve 1.0 g of *acetaldehyde R* in *2-propanol R* and dilute to 100.0 ml with the same solvent. Dilute 5.0 ml of the solution to 500.0 ml with *2-propanol R*. Prepare immediately before use.

Acetaldehyde standard solution (100 ppm $\text{C}_2\text{H}_4\text{O}$) R1. 5000101.

Dissolve 1.0 g of *acetaldehyde R* in *water R* and dilute to 100.0 ml with the same solvent. Dilute 5.0 ml of the solution to 500.0 ml with *water R*. Prepare immediately before use.

Aluminium standard solution (200 ppm Al). 5000200.

Dissolve in *water R* a quantity of *aluminium potassium sulphate R* equivalent to 0.352 g of $\text{AlK}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$. Add 10 ml of *dilute sulphuric acid R* and dilute to 100.0 ml with *water R*.

Aluminium standard solution (100 ppm Al). 5000203.

Immediately before use, dilute with *water R* to 10 times its volume a solution containing 8.947 g of *aluminium chloride R* in 1000.0 ml of *water R*.

Aluminium standard solution (10 ppm Al). 5000201.

Immediately before use, dilute with *water R* to 100 times its volume in a solution containing *aluminium nitrate R* equivalent to 1.39 g of $\text{Al}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$ in 100.0 ml.

Aluminium standard solution (2 ppm Al). 5000202.

Immediately before use, dilute with *water R* to 100 times its volume a solution containing *aluminium potassium sulphate R* equivalent to 0.352 g of $\text{AlK}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ and 10 ml of *dilute sulphuric acid R* in 100.0 ml.

Ammonium standard solution (100 ppm NH_4). 5000300.

Immediately before use, dilute to 25 ml with *water R* 10 ml of a solution containing *ammonium chloride R* equivalent to 0.741 g of NH_4Cl in 1000 ml.

Ammonium standard solution (2.5 ppm NH_4). 5000301.

Immediately before use, dilute with *water R* to 100 times its volume a solution containing *ammonium chloride R* equivalent to 0.741 g of NH_4Cl in 1000.0 ml.

Ammonium standard solution (1 ppm NH_4). 5000302.

Immediately before use, dilute ammonium standard solution (2.5 ppm NH_4) *R* to 2.5 times its volume with *water R*.

Antimony standard solution (100 ppm Sb). 5000401.

Dissolve *antimony potassium tartrate R* equivalent to 0.274 g of $\text{C}_4\text{H}_4\text{KO}_7\text{Sb} \cdot \frac{1}{2}\text{H}_2\text{O}$ in 500 ml of *1 M hydrochloric acid* and dilute the clear solution to 1000 ml with *water R*.

Antimony standard solution (1 ppm Sb). 5000400.

Dissolve *antimony potassium tartrate R* equivalent to 0.274 g of $\text{C}_4\text{H}_4\text{KO}_7\text{Sb} \cdot \frac{1}{2}\text{H}_2\text{O}$ in 20 ml of *hydrochloric acid R1* and dilute the clear solution to 100.0 ml with *water R*. To 10.0 ml of this solution add 200 ml of *hydrochloric acid R1* and dilute to 1000.0 ml with *water R*. To 100.0 ml of this solution add 300 ml of *hydrochloric acid R1* and dilute to 1000.0 ml with *water R*. Prepare the dilute solutions immediately before use.

Arsenic standard solution (10 ppm As). 5000500.

Immediately before use, dilute with *water R* to 100 times its volume a solution prepared by dissolving *arsenious trioxide R* equivalent to 0.330 g of As_2O_3 in 5 ml of *dilute sodium hydroxide solution R* and diluting to 250.0 ml with *water R*.

Arsenic standard solution (1 ppm As). 5000501.

Immediately before use, dilute *arsenic standard solution (10 ppm As) R* to 10 times its volume with *water R*.

Arsenic standard solution (0.1 ppm As). 5000502.

Immediately before use, dilute *arsenic standard solution (1 ppm As) R* to 10 times its volume with *water R*.

Barium standard solution (50 ppm Ba). 5000600.

Immediately before use, dilute with *distilled water R* to 20 times its volume a solution in *distilled water R* containing *barium chloride R* equivalent to 0.178 g of $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$ in 100.0 ml.

Bismuth standard solution (100 ppm Bi). 5005300.

Dissolve *bismuth R* equivalent to 0.500 g of Bi in 50 ml of *nitric acid R* and dilute to 500.0 ml with *water R*. Dilute the solution to 10 times its volume with *dilute nitric acid R* immediately before use.

Cadmium standard solution (0.1 per cent Cd). 5000700.

Dissolve *cadmium R* equivalent to 0.100 g of Cd in the smallest necessary amount of a mixture of equal volumes of *hydrochloric acid R* and *water R* and dilute to 100.0 ml with a 1 per cent *V/V* solution of *hydrochloric acid R*.

Cadmium standard solution (10 ppm Cd) . 5000701.

Immediately before use, dilute *cadmium standard solution (0.1 per cent Cd) R* to 100 times its volume with a 1 per cent *V/V* solution of *hydrochloric acid R*.

Calcium standard solution (400 ppm Ca). 5000800.

Immediately before use, dilute with *distilled water R* to 10 times its volume a solution in *distilled water R* containing *calcium carbonate R* equivalent to 1.000 g of CaCO_3 and 23 ml of *1 M hydrochloric acid* in 100.0 ml.

Calcium standard solution (100 ppm Ca). 5000801.

Immediately before use, dilute with *distilled water R* to 10 times its volume a solution in *distilled water R* containing *calcium carbonate R* equivalent to 0.624 g of CaCO_3 and 3 ml of *acetic acid R* in 250.0 ml.

Calcium standard solution (100 ppm Ca) R1. 5000804.

Immediately before use, dilute with *water R* to 10 times its volume a solution containing *anhydrous calcium chloride R* equivalent to 2.769 g of CaCl_2 in 1000.0 ml of *dilute hydrochloric acid R*.

Calcium standard solution (100 ppm Ca), alcoholic. 5000802.

Immediately before use, dilute with *alcohol R* to 10 times its volume a solution in *distilled water R* containing *calcium carbonate R* equivalent to 2.50 g of CaCO_3 and 12 ml of *acetic acid R* in 1000.0 ml.

Calcium standard solution (10 ppm Ca). 5000803.

Immediately before use, dilute with *distilled water R* to 100 times its volume a solution in *distilled water R* containing *calcium carbonate R* equivalent to 0.624 g of CaCO_3 and 3 ml of *acetic acid R* in 250.0 ml.

Chloride standard solution (50 ppm Cl). 5004100.

Immediately before use, dilute with *water R* to 10 times its volume a solution containing *sodium chloride R* equivalent to 0.824 g of NaCl in 1000.0 ml.

Chloride standard solution (8 ppm Cl). 5000900.

Immediately before use, dilute with *water R* to 100 times its volume a solution containing *sodium chloride R* equivalent to 1.32 g of NaCl in 1000.0 ml.

Chloride standard solution (5 ppm Cl). 5000901.

Immediately before use, dilute with *water R* to 100 times its volume a solution containing *sodium chloride R* equivalent to 0.824 g of NaCl in 1000.0 ml.

Chromium liposoluble standard solution (1000 ppm Cr). 5004600.

A chromium (metal) organic compound in an oil.

Chromium standard solution (0.1 per cent Cr). 5001002.

Dissolve *potassium dichromate R* equivalent to 2.83 g of $\text{K}_2\text{Cr}_2\text{O}_7$ in *water R* and dilute to 1000.0 ml with the same solvent.

Chromium standard solution (100 ppm Cr). 5001000.

Dissolve *potassium dichromate R* equivalent to 0.283 g of $\text{K}_2\text{Cr}_2\text{O}_7$ in *water R* and dilute to 1000.0 ml with the same solvent.

Chromium standard solution (0.1 ppm Cr). 5001001.

Immediately before use, dilute *chromium standard solution (100 ppm Cr) R* to 1000 times its volume with *water R*.

Cobalt standard solution (100 ppm Co). 5004300.

Dissolve *cobalt nitrate R* equivalent to 0.494 g of $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ in 500 ml of *1M nitric acid* and dilute the clear solution to 1000 ml with *water R*.

Copper liposoluble standard solution (1000 ppm Cu). 5004700.

A copper (metal) organic compound in an oil.

Copper standard solution (0.1 per cent Cu). 5001100.

Dissolve *copper sulphate R* equivalent to 0.393 g of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ in *water R* and dilute to 100.0 ml with the same solvent.

Copper standard solution (10 ppm Cu). 5001101.

Immediately before use, dilute *copper standard solution (0.1 per cent Cu) R* to 100 times its volume with *water R*.

Copper standard solution (0.1 ppm Cu). 5001102.

Immediately before use, dilute *copper standard solution (10 ppm Cu) R* to 100 times its volume with *water R*.

Ferrocyanide standard solution (100 ppm $\text{Fe}(\text{CN})_6$). 5001200.

Immediately before use, dilute with *water R* to 10 times its volume a solution containing *potassium ferrocyanide R* equivalent to 0.20 g of $\text{K}_4\text{Fe}(\text{CN})_6 \cdot 3\text{H}_2\text{O}$ in 100.0 ml.

Ferricyanide standard solution (50 ppm $\text{Fe}(\text{CN})_6$). 5001300.

Immediately before use, dilute with *water R* to 100 times its volume a solution containing *potassium ferricyanide R* equivalent to 0.78 g of $\text{K}_3\text{Fe}(\text{CN})_6$ in 100.0 ml.

Fluoride standard solution (10 ppm F). 5001400.

Dissolve in *water R* *sodium fluoride R* previously dried at 300 °C for 12 h, equivalent to 0.442 g of NaF, and dilute to 1000.0 ml with the same solvent (1 ml = 0.2 mg F). Store in a polyethylene container. Immediately before use, dilute the solution to 20 times its volume with *water R*.

Fluoride standard solution (1 ppm F). 5001401.

Immediately before use, dilute *fluoride standard solution (10 ppm F) R* to 10 times its volume with *water R*.

Formaldehyde standard solution (5 ppm CH_2O). 5001500.

Immediately before use, dilute with *water R* to 200 times its volume a solution containing 1.0 g of CH_2O per litre prepared from *formaldehyde solution R*.

Germanium standard solution (100 ppm Ge). 5004400.

Dissolve *ammonium hexafluorogermanate (IV) R* equivalent to 0.307 g of $(\text{NH}_4)_2\text{GeF}_6$ in a 0.01 per cent V/V solution of *hydrofluoric acid R*. Dilute the clear solution to 1000 ml with *water R*.

Glyoxal standard solution (20 ppm $\text{C}_2\text{H}_2\text{O}_2$). 5003700.

In a 100 ml graduated flask weigh a quantity of *glyoxal solution R* corresponding to 0.200 g of $\text{C}_2\text{H}_2\text{O}_2$ and make up to volume with *ethanol R*. Immediately before use dilute the solution to 100 times its volume with the same solvent.

Glyoxal standard solution (2 ppm $\text{C}_2\text{H}_2\text{O}_2$). 5003701.

Immediately before use, dilute *glyoxal standard solution (20 ppm $\text{C}_2\text{H}_2\text{O}_2$) R* to 10 times its volume with *ethanol R*.

Hydrogen peroxide standard solution (10 ppm H_2O_2). 5005200.

Dilute 10.0 ml of *dilute hydrogen peroxide solution R* to 300.0 ml with *water R*. Dilute 10.0 ml of this solution to 1000.0 ml with *water R*. Prepare immediately before use.

Iodide standard solution (10 ppm I). 5003800.

Immediately before use, dilute with *water R* to 100 times its volume a solution containing *potassium iodide R* equivalent to 0.131 g of KI in 100.0 ml.

Iron standard solution (0.1 per cent Fe). 5001605.

Dissolve 0.100 g of Fe in the smallest amount necessary of a mixture of equal volumes of *hydrochloric acid R* and *water R* and dilute to 100.0 ml with *water R*.

Iron standard solution (250 ppm Fe). 5001606.

Immediately before use, dilute with *water R* to 40 times its volume a solution containing 4.840 g of *ferric chloride R* in a 150 g/l solution of *hydrochloric acid R* diluted to 100.0 ml.

Iron standard solution (20 ppm Fe). 5001600.

Immediately before use, dilute with *water R* to 10 times its volume a solution containing *ferric ammonium sulphate R* equivalent to 0.863 g of $\text{FeNH}_4(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ and 25 ml of *dilute sulphuric acid R* in 500.0 ml.

Iron standard solution (10 ppm Fe). 5001601.

Immediately before use, dilute with *water R* to 100 times its volume a solution containing *ferrous ammonium sulphate R* equivalent to 7.022 g of $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$ and 25 ml of *dilute sulphuric acid R* in 1000.0 ml.

Iron standard solution (8 ppm Fe). 5001602.

Immediately before use, dilute with *water R* to 10 times its volume a solution containing 80 mg of *iron R* and 50 ml of *hydrochloric acid R* (220 g/l HCl) in 1000.0 ml.

Iron standard solution (2 ppm Fe). 5001603.

Immediately before use, dilute *iron standard solution (20 ppm Fe) R* to 10 times its volume with *water R*.

Iron standard solution (1 ppm Fe). 5001604.

Immediately before use, dilute *iron standard solution (20 ppm Fe) R* to 20 times its volume with *water R*.

Lead liposoluble standard solution (1000 ppm Pb). 5004800.

A lead (metal) organic compound in an oil.

Lead standard solution (0.1 per cent Pb). 5001700.

Dissolve *lead nitrate R* equivalent to 0.400 g of $\text{Pb}(\text{NO}_3)_2$ in *water R* and dilute to 250.0 ml with the same solvent.

Lead standard solution (0.1 per cent Pb) R1. 5005400.

Dissolve in *dilute lead-free nitric acid R* a quantity of *lead nitrate R* equivalent to 0.400 g of $\text{Pb}(\text{NO}_3)_2$ and dilute to 250.0 ml with the same solvent.

Lead standard solution (100 ppm Pb). 5001701.

Immediately before use, dilute *lead standard solution (0.1 per cent Pb) R* to 10 times its volume with *water R*.

Lead standard solution (10 ppm Pb). 5001702.

Immediately before use, dilute *lead standard solution (100 ppm Pb) R* to 10 times its volume with *water R*.

Lead standard solution (10 ppm Pb) R1. 5001706.

Immediately before use, dilute with *water R* to 10 times its volume a solution containing 0.160 g of *lead nitrate R* in 100 ml of *water R*, to which is added 1 ml of *lead-free nitric acid R* and dilute to 1000.0 ml.

Lead standard solution (10 ppm Pb) R2. 5005401.

Dilute *lead standard solution (0.1 per cent Pb) R1* to 100 times its volume with *dilute lead-free nitric acid R*. Use within 1 week.

Lead standard solution (2 ppm Pb). 5001703.

Immediately before use, dilute *lead standard solution (10 ppm Pb) R* to 5 times its volume with *water R*.

Lead standard solution (1 ppm Pb). 5001704.

Immediately before use, dilute *lead standard solution (10 ppm Pb) R* to 10 times its volume with *water R*.

Lead standard solution (0.5 ppm Pb). 5005402.

Dilute *lead standard solution (10 ppm Pb) R2* to 20 times its volume with *dilute lead-free nitric acid R*. Use within 1 day.

Lead standard solution (0.1 ppm Pb). 5001705.

Immediately before use, dilute *lead standard solution (1 ppm Pb) R* to 10 times its volume with *water R*.

Magnesium standard solution (100 ppm Mg). 5001800.

Immediately before use, dilute with *water R* to 10 times its volume a solution containing *magnesium sulphate R* equivalent to 1.010 g of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ in 100.0 ml.

Magnesium standard solution (10 ppm Mg). 5001801.

Immediately before use, dilute magnesium standard solution (100 ppm Mg) *R* to 10 times its volume with *water R*.

Magnesium standard solution (10 ppm Mg) R1. 5001802.

Immediately before use, dilute with *water R* to 100 times its volume a solution containing 8.365 g of *magnesium chloride R* in 1000.0 ml of *dilute hydrochloric acid R*.

Manganese standard solution (100 ppm Mn). 5004500.

Dissolve *manganese sulphate R* equivalent to 0.308 g of $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ in 500 ml of *1M nitric acid* and dilute the clear solution to 1000 ml with *water R*.

Mercury standard solution (1000 ppm Hg). 5001900.

Dissolve *mercuric chloride R* equivalent to 1.354 g of HgCl_2 in 50 ml of *dilute nitric acid R* and dilute to 1000.0 ml with *water R*.

Mercury standard solution (10 ppm Hg). 5001901.

Immediately before use, dilute with *water* to 100 times its volume a solution containing *mercuric chloride R* equivalent to 0.338 g of HgCl_2 in 250.0 ml.

Nickel liposoluble standard solution (1000 ppm Ni). 5004900.

A nickel (metal) organic compound in an oil.

Nickel standard solution (10 ppm Ni). 5002000.

Immediately before use, dilute with *water R* to 100 times its volume a solution containing *nickel sulphate R* equivalent to 4.78 g of $\text{NiSO}_4 \cdot 7\text{H}_2\text{O}$ in 1000.0 ml.

Nickel standard solution (0.2 ppm Ni). 5002002.

Immediately before use, dilute *nickel standard solution (10 ppm Ni) R* to 50 times its volume with *water R*.

Nickel standard solution (0.1 ppm Ni). 5002001.

Immediately before use, dilute *nickel standard solution (10 ppm Ni) R* to 100 times its volume with *water R*.

Nitrate standard solution (100 ppm NO_3). 5002100.

Immediately before use, dilute with *water R* to 10 times its volume a solution containing *potassium nitrate R* equivalent to 0.815 g of KNO_3 in 500.0 ml.

Nitrate standard solution (10 ppm NO_3). 5002101.

Immediately before use, dilute *nitrate standard solution (100 ppm NO_3) R* to 10 times its volume with *water R*.

Nitrate standard solution (2 ppm NO_3). 5002102.

Immediately before use, dilute *nitrate standard solution (10 ppm NO_3) R* to 5 times its volume with *water R*.

Palladium standard solution (500 ppm Pd). 5003600.

Dissolve 50.0 mg of *palladium R* in 9 ml of *hydrochloric acid R* and dilute to 100.0 ml with *water R*.

Palladium standard solution (20 ppm Pd). 5003602.

Dissolve 0.333 g of *palladium chloride R* in 2 ml of warm *hydrochloric acid R*. Dilute the solution to 1000.0 ml with a mixture of equal volumes of *dilute hydrochloric acid R* and *water R*. Immediately before use dilute to 10 times its volume with *water R*.

Palladium standard solution (0.5 ppm Pd). 5003601.

Dilute 1 ml of *palladium standard solution (500 ppm Pd) R* to 1000 ml with a mixture of 0.3 volumes of *nitric acid R* and 99.7 volumes of *water R*.

Phosphate standard solution (200 ppm PO₄). 5004200.

Dissolve *potassium dihydrogen phosphate R* equivalent to 0.286 g of KH₂PO₄ in *water R* and dilute to 1000.0 ml with the same solvent.

Phosphate standard solution (5 ppm PO₄). 5002200.

Immediately before use, dilute with *water R* to 100 times its volume a solution containing *potassium dihydrogen phosphate R* equivalent to 0.716 g of KH₂PO₄ in 1000.0 ml.

Platinum standard solution (30 ppm Pt). 5002300.

Immediately before use, dilute with *1 M hydrochloric acid* to 10 times its volume a solution containing 80 mg of *chloroplatinic acid R* in 100.0 ml of *1 M hydrochloric acid*.

Potassium standard solution (600 ppm K). 5005100.

Immediately before use, dilute with *water R* to 20 times its volume a solution containing *dipotassium sulphate R* equivalent to 2.676 g of K₂SO₄ in 100.0 ml.

Potassium standard solution (100 ppm K). 5002400.

Immediately before use, dilute with *water R* to 20 times its volume a solution containing *dipotassium sulphate R* equivalent to 0.446 g of K₂SO₄ in 100.0 ml.

Potassium standard solution (20 ppm K). 5002401.

Immediately before use, dilute *potassium standard solution (100 ppm K) R* to 5 times its volume with *water R*.

Selenium standard solution (100 ppm Se). 5002500.

Dissolve 0.100 g of *selenium R* in 2 ml of *nitric acid R*. Evaporate to dryness. Take up the residue in 2 ml of *water R* and evaporate to dryness; carry out three times. Dissolve the residue in 50 ml of *dilute hydrochloric acid R* and dilute to 1000.0 ml with the same acid.

Selenium standard solution (1 ppm Se). 5002501.

Immediately before use, dilute with *water R* to 40 times its volume a solution containing *selenious acid R* equivalent to 6.54 mg of H₂SeO₃ in 100.0 ml.

Silver standard solution (5 ppm Ag). 5002600.

Immediately before use, dilute with *water R* to 100 times its volume a solution containing *silver nitrate R* equivalent to 0.790 g of AgNO₃ in 1000.0 ml.

Sodium standard solution (200 ppm Na). 5002700.

Immediately before use, dilute with *water R* to 10 times its volume a solution containing *sodium chloride R* equivalent to 0.509 g of NaCl in 100.0 ml.

Sodium standard solution (50 ppm Na). 5002701.

Dilute the *sodium standard solution (200 ppm Na) R* to four times its volume with *water R*.

Strontium standard solution (1.0 per cent Sr). 5003900.

Cover with *water R*, *strontium carbonate R* equivalent to 1.6849 g of SrCO₃. Cautiously add *hydrochloric acid R* until all the solid has dissolved and there is no sign of further effervescence. Dilute to 100.0 ml with *water R*.

Sulphate standard solution (100 ppm SO₄). 5002802.

Immediately before use, dilute with *distilled water R* to 10 times its volume a solution in *distilled water R* containing *dipotassium sulphate R* equivalent to 0.181 g of K₂SO₄ in 100.0 ml.

Sulphate standard solution (10 ppm SO₄). 5002800.

Immediately before use, dilute with *distilled water R* to 100 times its volume a solution in *distilled water R* containing *dipotassium sulphate R* equivalent to 0.181 g of K₂SO₄ in 100.0 ml.

Sulphate standard solution (10 ppm SO₄) R1. 5002801.

Immediately before use, dilute with *alcohol (30 per cent V/V) R* to 100 times its volume a solution containing *dipotassium sulphate R* equivalent to 0.181 g of K₂SO₄ in 100.0 ml of *alcohol (30 per cent V/V) R*.

Sulphite standard solution (80 ppm SO₂). 5005500.

Dissolve 3.150 g of *anhydrous sodium sulphite R* in freshly prepared *distilled water R* and dilute to 100.0 ml with the same solvent. Dilute 0.5 ml to 100.0 ml with freshly prepared *distilled water R*.

Sulphite standard solution (1.5 ppm SO₂). 5002900.

Dissolve *sodium metabisulphite R* equivalent to 0.152 g of Na₂S₂O₅ in *water R* and dilute to 100.0 ml with the same solvent. Dilute 5.0 ml of this solution to 100.0 ml with *water R*. To 3.0 ml of the resulting solution, add 4.0 ml of *0.1 M sodium hydroxide* and dilute to 100.0 ml with *water R*.

Thallium standard solution (10 ppm Tl). 5003000.

Dissolve *thallous sulphate R* equivalent to 0.1235 g of Tl₂SO₄ in a 9 g/l solution of *sodium chloride R* and dilute to 1000.0 ml with the same solution. Dilute 10.0 ml of the solution to 100.0 ml with the 9 g/l solution of *sodium chloride R*.

Tin liposoluble standard solution (1000 ppm Sn). 5005000.

A tin metal organic compound in an oil.

Tin standard solution (5 ppm Sn). 5003100.

Dissolve *tin R* equivalent to 0.500 g of Sn in a mixture of 5 ml of *water R* and 25 ml of *hydrochloric acid R* and dilute to 1000.0 ml with *water R*. Dilute the solution to 100 times its volume with a 2.5 per cent V/V solution of *hydrochloric acid R* immediately before use.

Tin standard solution (0.1 ppm Sn). 5003101.

Immediately before use, dilute *tin standard solution (5 ppm Sn) R* to 50 times its volume with *water R*.

Titanium standard solution (100 ppm Ti). 5003200.

Dissolve 100.0 mg of *titanium R* in 100 ml of *hydrochloric acid R* diluted to 150 ml with *water R*, heating if necessary. Allow to cool and dilute to 1000 ml with *water R*.

Vanadium standard solution (1 g/l V). 5003300.

Dissolve in *water R* *ammonium vanadate R* equivalent to 0.230 g of NH₄VO₃ and dilute to 100.0 ml with the same solvent.

Zinc standard solution (5 mg/ml Zn). 5003400.

Dissolve 3.15 g of *zinc oxide R* in 15 ml of *hydrochloric acid R* and dilute to 500.0 ml with *water R*.

Zinc standard solution (100 ppm Zn). 5003401.

Immediately before use, dilute with *water R* to 10 times its volume a solution containing *zinc sulphate R* equivalent to 0.440 g of ZnSO₄·7H₂O and 1 ml of *acetic acid R* in 100.0 ml.

Zinc standard solution (10 ppm Zn). 5003402.

Immediately before use, dilute *zinc standard solution (100 ppm Zn) R* to 10 times its volume with *water R*.

Zinc standard solution (5 ppm Zn). 5003403.

Immediately before use, dilute *zinc standard solution (100 ppm Zn) R* to 20 times its volume with *water R*.

Zirconium standard solution (1 g/l Zr). 5003500.

Dissolve *zirconyl nitrate R* equivalent to 0.293 g of ZrO(NO₃)₂·2H₂O in a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R* and dilute to 100.0 ml with the same mixture of solvents.

01/2005:40103 Phosphate buffer solution pH 3.2. 4008100.

To 900 ml of a 4 g/l solution of *sodium dihydrogen phosphate R*, add 100 ml of a 2.5 g/l solution of *phosphoric acid R*. Adjust the pH (2.2.3) if necessary.

Phosphate buffer solution pH 3.2 R1. 4008500.

Adjust a 35.8 g/l solution of *disodium hydrogen phosphate R* to pH 3.2 (2.2.3) with *dilute phosphoric acid R*. Dilute 100.0 ml of the solution to 2000.0 ml with *water R*.

Buffer solution pH 3.5. 4000600.

Dissolve 25.0 g of *ammonium acetate R* in 25 ml of *water R* and add 38.0 ml of *hydrochloric acid R1*. Adjust the pH (2.2.3) if necessary with *dilute hydrochloric acid R* or *dilute ammonia R1*. Dilute to 100.0 ml with *water R*.

Phosphate buffer solution pH 3.5. 4000700.

Dissolve 68.0 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000.0 ml with the same solvent. Adjust the pH (2.2.3) with *phosphoric acid R*.

Buffer solution pH 3.6. 4000800.

To 250.0 ml of 0.2 M *potassium hydrogen phthalate R* add 11.94 ml of 0.2 M *hydrochloric acid*. Dilute to 1000.0 ml with *water R*.

Buffer solution pH 3.7. 4000900.

To 15.0 ml of *acetic acid R* add 60 ml of *alcohol R* and 20 ml of *water R*. Adjust to pH 3.7 (2.2.3) by the addition of *ammonia R*. Dilute to 100.0 ml with *water R*.

Buffered copper sulphate solution pH 4.0. 4001000.

Dissolve 0.25 g of *copper sulphate R* and 4.5 g of *ammonium acetate R* in *dilute acetic acid R* and dilute to 100.0 ml with the same solvent.

Acetate buffer solution pH 4.4. 4001100.

Dissolve 136 g of *sodium acetate R* and 77 g of *ammonium acetate R* in *water R* and dilute to 1000.0 ml with the same solvent; add 250.0 ml of *glacial acetic acid R* and mix.

Phthalate buffer solution pH 4.4. 4001200.

Dissolve 2.042 g of *potassium hydrogen phthalate R* in 50 ml of *water R*, add 7.5 ml of 0.2 M *sodium hydroxide* and dilute to 200.0 ml with *water R*.

Acetate buffer solution pH 4.5. 4012500.

Dissolve 77.1 g of *ammonium acetate R* in *water R*. Add 70 ml of *glacial acetic acid R* and dilute to 1000.0 ml with *water R*.

0.05 M Phosphate buffer solution pH 4.5. 4009000.

Dissolve 6.80 g of *potassium dihydrogen phosphate R* in 1000.0 ml of *water R*. The pH (2.2.3) of the solution is 4.5.

Sodium acetate buffer solution pH 4.5. 4010100.

Dissolve 63 g of *anhydrous sodium acetate R* in *water R*, add 90 ml *acetic acid R* and adjust to pH 4.5, and dilute to 1000 ml with *water R*.

Acetate buffer solution pH 4.6. 4001400.

Dissolve 5.4 g of *sodium acetate R* in 50 ml of *water R*, add 2.4 g of *glacial acetic acid R* and dilute to 100.0 ml with *water R*. Adjust the pH (2.2.3) if necessary.

Succinate buffer solution pH 4.6. 4001500.

Dissolve 11.8 g of *succinic acid R* in a mixture of 600 ml of *water R* and 82 ml of 1 M *sodium hydroxide* and dilute to 1000.0 ml with *water R*.

4.1.3. BUFFER SOLUTIONS**Buffered acetone solution. 4000100.**

Dissolve 8.15 g of *sodium acetate R* and 42 g of *sodium chloride R* in *water R*, add 68 ml of 0.1 M *hydrochloric acid* and 150 ml of *acetone R* and dilute to 500 ml with *water R*.

Buffer solution pH 2.0. 4000200.

Dissolve 6.57 g of *potassium chloride R* in *water R* and add 119.0 ml of 0.1 M *hydrochloric acid*. Dilute to 1000.0 ml with *water R*.

Phosphate buffer solution pH 2.0. 4007900.

Dissolve 8.95 g of *disodium hydrogen phosphate R* and 3.40 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000.0 ml with the same solvent. If necessary adjust the pH (2.2.3) with *phosphoric acid R*.

Sulphate buffer solution pH 2.0. 4008900.

Dissolve 132.1 g of *ammonium sulphate R* in *water R* and dilute to 500.0 ml with the same solvent (Solution I). Carefully and with constant cooling stir 14 ml of sulphuric acid R into about 400 ml of *water R*; allow to cool and dilute to 500.0 ml with *water R* (Solution II). Mix equal volumes of solutions I and II. Adjust the pH (2.2.3) if necessary.

Buffer solution pH 2.2. 4010500.

Mix of 6.7 ml of *phosphoric acid R* with 50.0 ml of a 4 per cent solution of *dilute sodium hydroxide solution R* and dilute to 1000.0 ml with *water R*.

Buffer solution pH 2.5. 4000300.

Dissolve 100 g of *potassium dihydrogen phosphate R* in 800 ml of *water R*; adjust to pH 2.5 (2.2.3) with *hydrochloric acid R* and dilute to 1000.0 ml with *water R*.

Buffer solution pH 2.5 R1. 4000400.

To 4.9 g of *dilute phosphoric acid R* add 250 ml of *water R*. Adjust the pH (2.2.3) with *dilute sodium hydroxide solution R* and dilute to 500.0 ml with *water R*.

Phosphate buffer solution pH 2.8. 4010600.

Dissolve 7.8 g of *sodium dihydrogen phosphate R* in 900 ml of *water R*, adjust to pH 2.8 (2.2.3) with *phosphoric acid R* and dilute to 1000 ml with the same solvent.

Buffer solution pH 3.0. 4008000.

Dissolve 21.0 g of *citric acid R* in 200 ml of 1 M *sodium hydroxide* and dilute to 1000 ml with *water R*. Dilute 40.3 ml of this solution to 100.0 ml with 0.1 M *hydrochloric acid*.

Phosphate buffer solution pH 3.0. 4000500.

Mix 0.7 ml of *phosphoric acid R* with 100 ml of *water R*. Dilute to 900 ml with the same solvent. Adjust to pH 3.0 (2.2.3) with *strong sodium hydroxide solution R* and dilute to 1000 ml with *water R*.

0.1 M Phosphate buffer solution pH 3.0. 4011500.

Dissolve 12.0 g of *anhydrous sodium dihydrogen phosphate R* in *water R*, adjust the pH (2.2.3) with *dilute phosphoric acid R1* and dilute to 1000 ml with *water R*.

Phosphate buffer solution pH 3.0 R1. 4010000.

Dissolve 3.40 g of *potassium dihydrogen phosphate R* in 900 ml of *water R*. Adjust to pH 3.0 (2.2.3) with *phosphoric acid R* and dilute to 1000.0 ml with *water R*.

Acetate buffer solution pH 4.7. 4001600.

Dissolve 136.1 g of *sodium acetate R* in 500 ml of *water R*. Mix 250 ml of this solution with 250 ml of *dilute acetic acid R*. Shake twice with a freshly prepared, filtered, 0.1 g/l solution of *dithizone R* in *chloroform R*. Shake with *carbon tetrachloride R* until the extract is colourless. Filter the aqueous layer to remove traces of carbon tetrachloride.

Acetate buffer solution pH 5.0. 4009100.

To 120 ml of a 6 g/l solution of *glacial acetic acid R* add 100 ml of 0.1 M *potassium hydroxide* and about 250 ml of *water R*. Mix. Adjust the pH to 5.0 with a 6 g/l solution of *acetic acid R* or with 0.1 M *potassium hydroxide* and dilute to 1000.0 ml with *water R*.

Citrate buffer solution pH 5.0. 4010700.

Prepare a solution containing 20.1 g/l of *citric acid R* and 8.0 g/l of *sodium hydroxide R*. Adjust the pH with *dilute hydrochloric acid R*.

Phosphate buffer solution pH 5.0. 4011300.

Dissolve 2.72 g of *potassium dihydrogen phosphate R* in 800 ml of *water R*. Adjust the pH (2.2.3) with 1 M *potassium hydroxide* and dilute to 1000 ml with *water R*.

Buffer solution pH 5.2. 4001700.

Dissolve 1.02 g of *potassium hydrogen phthalate R* in 30.0 ml of 0.1 M *sodium hydroxide*. Dilute to 100.0 ml with *water R*.

0.067 M Phosphate buffer solution pH 5.4. 4012000.

Mix appropriate volumes of a 23.99 g/l solution of *disodium hydrogen phosphate R* with a 9.12 g/l solution of *sodium dihydrogen phosphate monohydrate R* to obtain pH 5.4 (2.2.3).

Acetate-edetate buffer solution pH 5.5. 4001900.

Dissolve 250 g of *ammonium acetate R* and 15 g *sodium edetate R* in 400 ml of *water R* and add 125 ml of *glacial acetic acid R*.

Buffer solution pH 5.5. 4001800.

Dissolve 54.4 g of *sodium acetate R* in 50 ml of *water R*, heating to 35 °C if necessary. After cooling, slowly add 10 ml of *anhydrous acetic acid R*. Shake and dilute to 100.0 ml with *water R*.

Phosphate buffer solution pH 5.5. 4002000.

Solution I. Dissolve 13.61 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000.0 ml with the same solvent.

Solution II. Dissolve 35.81 g of *disodium hydrogen phosphate R* in *water R* and dilute to 1000.0 ml with the same solvent.

Mix 96.4 ml of solution I and 3.6 ml of solution II.

Phosphate-citrate buffer solution pH 5.5. 4008700.

Mix 56.85 ml of a 28.4 g/l solution of *anhydrous disodium hydrogen phosphate R* and 43.15 ml of a 21 g/l solution of *citric acid R*.

Phosphate buffer solution pH 5.6. 4011200.

Solution I. Dissolve 0.908 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 100.0 ml with the same solvent.

Solution II. Dissolve 1.161 g of *dipotassium hydrogen phosphate R* in *water R* and dilute to 100.0 ml with the same solvent.

Mix 94.4 ml of solution I and 5.6 ml of solution II. If necessary, adjust to pH 5.6 (2.2.3) using solution I or solution II.

Phosphate buffer solution pH 5.8. 4002100.

Dissolve 1.19 g of *disodium hydrogen phosphate dihydrate R* and 8.25 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000.0 ml with the same solvent.

Acetate buffer solution pH 6.0. 4002200.

Dissolve 100 g of *ammonium acetate R* in 300 ml of *water R*, add 4.1 ml of *glacial acetic acid R*, adjust the pH (2.2.3) if necessary using *ammonia R* or *acetic acid R* and dilute to 500.0 ml with *water R*.

Diethylammonium phosphate buffer solution pH 6.0. 4002300.

Dilute 68 ml of *phosphoric acid R* to 500 ml with *water R*. To 25 ml of this solution add 450 ml of *water R* and 6 ml of *diethylamine R*, adjust to pH 6 ± 0.05 (2.2.3), if necessary, using *diethylamine R* or *phosphoric acid R* and dilute to 500.0 ml with *water R*.

Phosphate buffer solution pH 6.0. 4002400.

Mix 63.2 ml of a 71.5 g/l solution of *disodium hydrogen phosphate R* and 36.8 ml of a 21 g/l solution of *citric acid R*.

Phosphate buffer solution pH 6.0 R1. 4002500.

Dissolve 6.8 g of *sodium dihydrogen phosphate R* in *water R* and dilute to 1000.0 ml with *water R*. Adjust the pH (2.2.3) with *strong sodium hydroxide solution R*.

Phosphate buffer solution pH 6.0 R2. 4002600.

To 250.0 ml of 0.2 M *potassium dihydrogen phosphate R* add 28.5 ml of 0.2 M *sodium hydroxide* and dilute to 1000.0 ml with *water R*.

Phosphate buffer solution pH 6.4. 4002800.

Dissolve 2.5 g of *disodium hydrogen phosphate R*, 2.5 g of *sodium dihydrogen phosphate R* and 8.2 g of *sodium chloride R* in 950 ml of *water R*. Adjust the pH (2.2.3) of the solution to 6.4 with 1 M *sodium hydroxide* or 1 M *hydrochloric acid*, if necessary. Dilute to 1000.0 ml with *water R*.

0.5 M Phthalate buffer solution pH 6.4. 4009200.

Dissolve 100 g of *potassium hydrogen phthalate R* in *water R* and dilute to 1000.0 ml with the same solvent. Adjust the pH (2.2.3) if necessary, using *strong sodium hydroxide solution R*.

Buffer solution pH 6.5. 4002900.

Dissolve 60.5 g of *disodium hydrogen phosphate R* and 46 g of *potassium dihydrogen phosphate R* in *water R*. Add 100 ml of 0.02 M *sodium edetate* and 20 mg of *mercuric chloride R* and dilute to 1000.0 ml with *water R*.

Imidazole buffer solution pH 6.5. 4003000.

Dissolve 6.81 g of *imidazole R*, 1.23 g of *magnesium sulphate R* and 0.73 g of *calcium sulphate R* in 752 ml of 0.1 M *hydrochloric acid*. Adjust the pH (2.2.3) if necessary and dilute to 1000.0 ml with *water R*.

0.1 M phosphate buffer solution pH 6.5. 4010800.

Dissolve 13.80 g of *sodium dihydrogen phosphate monohydrate R* in 900 ml of *distilled water R*. Adjust the pH (2.2.3) using a 400 g/l solution of *sodium hydroxide R*. Dilute to 1000 ml with *distilled water R*.

Buffer solution pH 6.6. 4003100.

To 250.0 ml of 0.2 M *potassium dihydrogen phosphate R* add 89.0 ml of 0.2 M *sodium hydroxide*. Dilute to 1000.0 ml with *water R*.

Phosphate buffered saline pH 6.8. 4003200.

Dissolve 1.0 g of *potassium dihydrogen phosphate R*, 2.0 g of *dipotassium hydrogen phosphate R* and 8.5 g of *sodium chloride R* in 900 ml of *water R*, adjust the pH (2.2.3) if necessary and dilute to 1000.0 ml with the same solvent.

Phosphate buffer solution pH 6.8. 4003300.

Mix 77.3 ml of a 71.5 g/l solution of *disodium hydrogen phosphate R* with 22.7 ml of a 21 g/l solution of *citric acid R*.

Phosphate buffer solution pH 6.8 R1. 4003400.

To 51.0 ml of a 27.2 g/l solution of *potassium dihydrogen phosphate R* add 49.0 ml of a 71.6 g/l solution of *disodium hydrogen phosphate R*. Adjust the pH (2.2.3) if necessary.

Storage: at 2 °C to 8 °C.

1 M tris-hydrochloride buffer solution pH 6.8. 4009300.

Dissolve 60.6 g of *tris(hydroxymethyl)aminomethane R* in 400 ml of *water R*. Adjust the pH (2.2.3) with *hydrochloric acid R* and dilute to 500.0 ml with *water R*.

Buffer solution pH 7.0. 4003500.

To 1000 ml of a solution containing 18 g/l of *disodium hydrogen phosphate R* and 23 g/l of *sodium chloride R* add sufficient (about 280 ml) of a solution containing 7.8 g/l of *sodium dihydrogen phosphate R* and 23 g/l of *sodium chloride R* to adjust the pH (2.2.3). Dissolve in the solution sufficient *sodium azide R* to give a 0.2 g/l solution.

Maleate buffer solution pH 7.0. 4003600.

Dissolve 10.0 g of *sodium chloride R*, 6.06 g of *tris(hydroxymethyl)aminomethane R* and 4.90 g of *maleic anhydride R* in 900 ml of *water R*. Adjust the pH (2.2.3) using a 170 g/l solution of *sodium hydroxide R*. Dilute to 1000.0 ml with *water R*.

Storage: at 2 °C to 8 °C; use within 3 days.

0.025 M Phosphate buffer solution pH 7.0. 4009400.

Mix 1 volume of 0.063 M *phosphate buffer solution pH 7.0 R* with 1.5 volumes of *water R*.

0.03 M Phosphate buffer solution pH 7.0. 4010300.

Dissolve 5.2 g of *dipotassium hydrogen phosphate R* in 900 ml of *water for chromatography R*. Adjust the solution to pH 7.0 ± 0.1 using *phosphoric acid R* and dilute to 1000 ml with *water for chromatography R*.

0.05 M Phosphate buffer solution pH 7.0. 4012400.

Mix 34 ml of *water R* and 100 ml of 0.067 M *phosphate buffer solution pH 7.0 R*.

0.063 M Phosphate buffer solution pH 7.0. 4009500.

Dissolve 5.18 g of *anhydrous disodium hydrogen phosphate R* and 3.65 g of *sodium dihydrogen phosphate monohydrate R* in 950 ml of *water R* and adjust the pH (2.2.3) with *phosphoric acid R*; dilute to 1000.0 ml with *water R*.

0.067 M Phosphate buffer solution pH 7.0. 4003800.

Solution I. Dissolve 0.908 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 100.0 ml with the same solvent.

Solution II. Dissolve 2.38 g of *disodium hydrogen phosphate R* in *water R* and dilute to 100.0 ml with the same solvent.

Mix 38.9 ml of *solution I* and 61.1 ml of *solution II*. Adjust the pH (2.2.3) if necessary.

0.1 M Phosphate buffer solution pH 7.0. 4008200.

Dissolve 1.361 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 100.0 ml with the same solvent. Adjust the pH (2.2.3) using a 35 g/l solution of *disodium hydrogen phosphate R*.

Phosphate buffer solution pH 7.0. 4003700.

Mix 82.4 ml of a 71.5 g/l solution of *disodium hydrogen phosphate R* with 17.6 ml of a 21 g/l solution of *citric acid R*.

Phosphate buffer solution pH 7.0 R1. 4003900.

Mix 250.0 ml of 0.2 M *potassium dihydrogen phosphate R* and 148.2 ml of a 8 g/l solution of *sodium hydroxide R*, adjust the pH (2.2.3) if necessary. Dilute to 1000.0 ml with *water R*.

Phosphate buffer solution pH 7.0 R2. 4004000.

Mix 50.0 ml of a 136 g/l solution of *potassium dihydrogen phosphate R* with 29.5 ml of 1 M *sodium hydroxide* and dilute to 100.0 ml with *water R*. Adjust the pH (2.2.3) to 7.0 ± 0.1.

Phosphate buffer solution pH 7.0 R3. 4008600.

Dissolve 5 g of *potassium dihydrogen phosphate R* and 11 g of *dipotassium hydrogen phosphate R* in 900 ml of *water R*. Adjust to pH 7.0 (2.2.3) with *dilute phosphoric acid R* or *dilute sodium hydroxide solution R*. Dilute to 1000 ml with *water R* and mix.

Phosphate buffer solution pH 7.0 R4. 4010200.

Dissolve 28.4 g of *anhydrous disodium hydrogen phosphate R* and 18.2 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 500 ml with the same solvent.

Phosphate buffer solution pH 7.0 R5. 4011400.

Dissolve 28.4 g of *anhydrous disodium hydrogen phosphate R* in 800 ml of *water R*. Adjust the pH (2.2.3) using a 30 per cent *m/m* solution of *phosphoric acid R* and dilute to 1000 ml with *water R*.

Tetrabutylammonium buffer solution pH 7.0. 4010900.

Dissolve 6.16 g of *ammonium acetate R* in a mixture of 15 ml of *tetrabutylammonium hydroxide solution (400 g/l) R* and 185 ml of *water R*. Adjust the pH (2.2.3) with *nitric acid R*.

Buffered salt solution pH 7.2. 4004300.

Dissolve in *water R* 8.0 g of *sodium chloride R*, 0.2 g of *potassium chloride R*, 0.1 g of *anhydrous calcium chloride R*, 0.1 g of *magnesium chloride R*, 3.18 g of *disodium hydrogen phosphate R* and 0.2 g of *potassium dihydrogen phosphate R* and dilute to 1000.0 ml with *water R*.

Buffer solution pH 7.2. 4004100.

To 250.0 ml of 0.2 M *potassium dihydrogen phosphate R* add 175.0 ml of 0.2 M *sodium hydroxide*. Dilute to 1000.0 ml with *water R*. Adjust the pH (2.2.3) if necessary.

Phosphate-albumin buffered saline pH 7.2. 4004400.

Dissolve 10.75 g of *disodium hydrogen phosphate R*, 7.6 g of *sodium chloride R* and 10 g of *bovine albumin R* in *water R* and dilute to 1000.0 ml with the same solvent. Immediately before use adjust the pH (2.2.3) using *dilute sodium hydroxide solution R* or *dilute phosphoric acid R*.

Phosphate-albumin buffered saline pH 7.2 R1. 4009600.

Dissolve 10.75 g of *disodium hydrogen phosphate R*, 7.6 g of *sodium chloride R* and 1 g of *bovine albumin R* in *water R* and dilute to 1000.0 ml with the same solvent. Immediately before use adjust the pH (2.2.3) using *dilute sodium hydroxide solution R* or *dilute phosphoric acid R*.

Phosphate buffer solution pH 7.2. 4004200.

Mix 87.0 ml of a 71.5 g/l solution of *disodium hydrogen phosphate R* with 13.0 ml of a 21 g/l solution of *citric acid R*.

Imidazole buffer solution pH 7.3. 4004500.

Dissolve 3.4 g of *imidazole R* and 5.8 g of *sodium chloride R* in *water R*, add 18.6 ml of 1 M *hydrochloric acid* and dilute to 1000.0 ml with *water R*. Adjust the pH (2.2.3) if necessary.

Barbital buffer solution pH 7.4. 4004700.

Mix 50 ml of a solution in *water R* containing 19.44 g/l of *sodium acetate R* and 29.46 g/l of *barbital sodium R* with 50.5 ml of 0.1 M *hydrochloric acid*, add 20 ml of an 85 g/l of *sodium chloride R* and dilute to 250 ml with *water R*.

Buffer solution pH 7.4. 4004600.

Dissolve 0.6 g of *potassium dihydrogen phosphate R*, 6.4 g of *disodium hydrogen phosphate R* and 5.85 g of *sodium chloride R* in *water R*, and dilute to 1000.0 ml with the same solvent. Adjust the pH (2.2.3) if necessary.

Phosphate buffered saline pH 7.4. 4005000.

Dissolve 2.38 g of *disodium hydrogen phosphate R*, 0.19 g of *potassium dihydrogen phosphate R* and 8.0 g of *sodium chloride R* in *water*. Dilute to 1000.0 ml with the same solvent. Adjust the pH (2.2.3) if necessary.

Phosphate buffer solution pH 7.4. 4004800.

Add 250.0 ml of 0.2 M *potassium dihydrogen phosphate R* to 393.4 ml of 0.1 M *sodium hydroxide*.

Tris(hydroxymethyl)aminomethane buffer solution pH 7.4. 4012100.

Dissolve 30.3 g of *tris(hydroxymethyl)aminomethane R* in approximately 200 ml of *water R*. Add 183 ml of 1 M *hydrochloric acid*. Dilute to 500.0 ml with *water R*. Note: the pH is 7.7-7.8 at room temperature and 7.4 at 37 °C. This solution is stable for several months at 4 °C.

Tris(hydroxymethyl)aminomethane sodium chloride buffer solution pH 7.4. 4004900.

Dissolve 6.08 g of *tris(hydroxymethyl)aminomethane R*, 8.77 g of *sodium chloride R* in 500 ml of *distilled water R*. Add 10.0 g of *bovine albumin R*. Adjust the pH (2.2.3) using *hydrochloric acid R*. Dilute to 1000.0 ml with *distilled water R*.

Tris(hydroxymethyl)aminomethane sodium chloride buffer solution pH 7.4 R1. 4012200.

Dissolve 0.1 g of *bovine albumin R* in a mixture containing 2 ml of *tris(hydroxymethyl)aminomethane buffer solution pH 7.4 R* and 50 ml of a 5.84 mg/ml solution of *sodium chloride R*. Dilute to 100.0 ml with *water R*.

Borate buffer solution pH 7.5. 4005200.

Dissolve 2.5 g of *sodium chloride R*, 2.85 g of *disodium tetraborate R* and 10.5 g of *boric acid R* in *water R* and dilute to 1000.0 ml with the same solvent. Adjust the pH (2.2.3) if necessary.

Storage: at 2 °C to 8 °C.

Buffer (HEPES) solution pH 7.5. 4009700.

Dissolve 2.38 g of 2-[4-(2-hydroxyethyl)piperazin-1-yl]ethanesulphonic acid *R* in about 90 ml of *water R*. Adjust the pH to 7.5 with *sodium hydroxide solution R*. Dilute to 100 ml with *water R*.

0.2 M Phosphate buffer solution pH 7.5. 4005400.

Dissolve 27.22 g of *potassium dihydrogen phosphate R* in 930 ml of *water R*, adjust to pH 7.5 (2.2.3) with a 300 g/l solution of *potassium hydroxide R* and dilute to 1000.0 ml with *water R*.

0.33 M Phosphate buffer solution pH 7.5. 4005300.

Solution I. Dissolve 119.31 g of *disodium hydrogen phosphate R* in *water R* and dilute to 1000.0 ml with the same solvent.

Solution II. Dissolve 45.36 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000.0 ml with the same solvent.

Mix 85 ml of solution I and 15 ml of solution II. Adjust the pH (2.2.3) if necessary.

0.05 M Tris-hydrochloride buffer solution pH 7.5. 4005600.

Dissolve 6.057 g of *tris(hydroxymethyl)aminomethane R* in *water R* and adjust the pH (2.2.3) with *hydrochloric acid R*. Dilute to 1000.0 ml with *water R*.

Tris(hydroxymethyl)aminomethane buffer solution pH 7.5. 4005500.

Dissolve 7.27 g of *tris(hydroxymethyl)aminomethane R* and 5.27 g of *sodium chloride R* in *water R*, and adjust the pH (2.2.3) if necessary. Dilute to 1000.0 ml with *water R*.

Sodium citrate buffer solution pH 7.8 (0.034 M sodium citrate, 0.101 M sodium chloride). 4009800.

Dissolve 10.0 g of *sodium citrate R* and 5.90 g of *sodium chloride R* in 900 ml of *water R*. Adjust the pH (2.2.3) by addition of *hydrochloric acid R* and dilute to 1000 ml with *water R*.

0.0015 M Borate buffer solution pH 8.0. 4006000.

Dissolve 0.572 g of *disodium tetraborate R* and 2.94 g of *calcium chloride R* in 800 ml of *water R*. Adjust the pH (2.2.3) with 1 M *hydrochloric acid*. Dilute to 1000.0 ml with *water R*.

Buffer solution pH 8.0. 4005900.

To 50.0 ml of 0.2 M *potassium dihydrogen phosphate R* add 46.8 ml of 0.2 M *sodium hydroxide*. Dilute to 200.0 ml with *water R*.

Buffer solution pH 8.0 R1. 4010400.

Dissolve 20 g of *dipotassium hydrogen phosphate R* in 900 ml of *water R*. Adjust the pH (2.2.3) with *phosphoric acid R*. Dilute to 1000 ml with *water R*.

0.02 M Phosphate buffer solution pH 8.0. 4006100.

To 50.0 ml of 0.2 M *potassium dihydrogen phosphate R* add 46.8 ml of 0.2 M *sodium hydroxide*. Dilute to 500.0 ml with *water R*.

0.1 M Phosphate buffer solution pH 8.0. 4008400.

Dissolve 0.523 g of *potassium dihydrogen phosphate R* and 16.73 g of *dipotassium hydrogen phosphate R* in *water R* and dilute to 1000.0 ml with the same solvent.

1 M Phosphate buffer solution pH 8.0. 4007800.

Dissolve 136.1 g of *potassium dihydrogen phosphate R* in *water R*, adjust the pH (2.2.3) with 1 M *sodium hydroxide*. Dilute to 1000.0 ml with *water R*.

Tris-hydrochloride buffer solution pH 8.0. 4012300.

Dissolve 1.21 g of *tris(hydroxymethyl)aminomethane R* and 29.4 mg of *calcium chloride R* in *water R*. Adjust the pH (2.2.3) with *1 M hydrochloric acid* and dilute to 100.0 ml with *water R*.

Tris(hydroxymethyl)aminomethane buffer solution pH 8.1. 4006200.

Dissolve 0.294 g of *calcium chloride R* in 40 ml of *tris(hydroxymethyl)aminomethane solution R* and adjust the pH (2.2.3) with *1 M hydrochloric acid*. Dilute to 100.0 ml with *water R*.

Tris-glycine buffer solution pH 8.3. 4006300.

Dissolve 6.0 g of *tris(hydroxymethyl)aminomethane R* and 28.8 g of *glycine R* in *water R* and dilute to 1000.0 ml with the same solvent. Dilute 1 volume to 10 volumes with *water R* immediately before use.

Tris-hydrochloride buffer solution pH 8.3. 4011800.

Dissolve 9.0 g of *tris(hydroxymethyl)aminomethane R* in 2.9 litres of *water R*. Adjust the pH (2.2.3) with *1 M hydrochloric acid*. Adjust the volume to 3 litres with *water R*.

Barbital buffer solution pH 8.4. 4006400.

Dissolve 8.25 g of *barbital sodium R* in *water R* and dilute to 1000.0 ml with the same solvent.

Tris-EDTA BSA buffer solution pH 8.4. 4006500.

Dissolve 6.1 g of *tris(hydroxymethyl)aminomethane R*, 2.8 g of *sodium edetate R*, 10.2 g of *sodium chloride R* and 10 g of *bovine albumin R* in *water R*, adjust to pH 8.4 (2.2.3) using *1 M hydrochloric acid* and dilute to 1000.0 ml with *water R*.

Tris(hydroxymethyl)aminomethane EDTA buffer solution pH 8.4. 4006600.

Dissolve 5.12 g of *sodium chloride R*, 3.03 g of *tris(hydroxymethyl)aminomethane R* and 1.40 g of *sodium edetate R* in 250 ml of *distilled water R*. Adjust the pH (2.2.3) to 8.4 using *hydrochloric acid R*. Dilute to 500.0 ml with *distilled water R*.

Tris acetate buffer solution pH 8.5. 4006700.

Dissolve 0.294 g of *calcium chloride R* and 12.11 g of *tris(hydroxymethyl)aminomethane R* in *water R*. Adjust the pH (2.2.3) with *acetic acid R*. Dilute to 1000.0 ml with *water R*.

Barbital buffer solution pH 8.6 R1. 4006900.

Dissolve in *water R* 1.38 g of *barbital R*, 8.76 g of *barbital sodium R* and 0.38 g of *calcium lactate R* and dilute to 1000.0 ml with the same solvent.

1.5 M tris-hydrochloride buffer solution pH 8.8. 4009900.

Dissolve 90.8 g of *tris(hydroxymethyl)aminomethane R* in 400 ml of *water R*. Adjust the pH (2.2.3) with *hydrochloric acid R* and dilute to 500.0 ml with *water R*.

Buffer (phosphate) solution pH 9.0. 4008300.

Dissolve 1.74 g of *potassium dihydrogen phosphate R* in 80 ml of *water R*, adjust the pH (2.2.3) with *1 M potassium hydroxide* and dilute to 100.0 ml with *water R*.

Buffer solution pH 9.0. 4007000.

Solution I. Dissolve 6.18 g of *boric acid R* in *0.1 M potassium chloride R* and dilute to 1000.0 ml with the same solvent.

Solution II. *0.1 M sodium hydroxide.*

Mix 1000.0 ml of solution I and 420.0 ml of solution II.

Buffer solution pH 9.0 R1. 4007100.

Dissolve 6.20 g of *boric acid R* in 500 ml of *water R* and adjust the pH (2.2.3) with *1 M sodium hydroxide* (about 41.5 ml). Dilute to 1000.0 ml with *water R*.

Ammonium chloride buffer solution pH 9.5. 4007200.

Dissolve 33.5 g of *ammonium chloride R* in 150 ml of *water R*, add 42.0 ml of *concentrated ammonia R* and dilute to 250.0 ml with *water R*.

Storage: in a polyethylene container.

Ammonium chloride buffer solution pH 10.0. 4007300.

Dissolve 5.4 g of *ammonium chloride R* in 20 ml of *water R*, add 35.0 ml of *ammonia R* and dilute to 100.0 ml with *water R*.

Diethanolamine buffer solution pH 10.0. 4007500.

Dissolve 96.4 g of *diethanolamine R* in *water R* and dilute to 400 ml with the same solvent. Add 0.5 ml of an 186 g/l solution of *magnesium chloride R* and adjust the pH (2.2.3) with *1 M hydrochloric acid*. Dilute to 500.0 ml with *water R*.

0.1 M Ammonium carbonate buffer solution pH 10.3. 4011900.

Dissolve 7.91 g of *ammonium carbonate R* in 800 ml of *water R*. Adjust the pH (2.2.3) with *dilute sodium hydroxide solution R*. Dilute to 1000.0 ml with *water R*.

Ammonium chloride buffer solution pH 10.4. 4011000.

Dissolve 70 g of *ammonium chloride R* in 200 ml of *water R*, add 330 ml of *concentrated ammonia R* and dilute to 1000.0 ml with *water R*. If necessary, adjust to pH 10.4 with *ammonia R*.

Borate buffer solution pH 10.4. 4011100.

Dissolve 24.64 g of *boric acid R* in 900 ml of *distilled water R*. Adjust the pH (2.2.3) using a 400 g/l solution of *sodium hydroxide R*. Dilute to 1000 ml with *distilled water R*.

Buffer solution pH 10.9. 4007600.

Dissolve 6.75 g of *ammonium chloride R* in *ammonia R* and dilute to 100.0 ml with the same solvent.

Total-ionic-strength-adjustment buffer. 4007700.

Dissolve 58.5 g of *sodium chloride R*, 57.0 ml of *glacial acetic acid R*, 61.5 g of *sodium acetate R* and 5.0 g of *cyclohexylene-dinitrilotetra-acetic acid R* in *water R* and dilute to 500.0 ml with the same solvent. Adjust to pH 5.0 to 5.5 with a 335 g/l solution of *sodium hydroxide R* and dilute to 1000.0 ml with *distilled water R*.

Total-ionic-strength-adjustment buffer R1. 4008800.

Solution (a). Dissolve 210 g of *citric acid R* in 400 ml of *distilled water R*. Adjust to pH 7.0 (2.2.3) with *concentrated ammonia R*. Dilute to 1000.0 ml with *distilled water R*.

Solution (b). Dissolve 132 g of *ammonium phosphate R* in *distilled water R* and dilute to 1000.0 ml with the same solvent.

Solution (c). To a suspension of 292 g of (ethylenedinitrilo)tetra-acetic acid *R* in about 500 ml of distilled water *R*, add about 200 ml of concentrated ammonia *R* to dissolve. Adjust the pH to 6 to 7 (2.2.3) with concentrated ammonia *R*. Dilute to 1000.0 ml with distilled water *R*.

Mix equal volumes of solution (a), (b), and (c) and adjust to pH 7.5 with concentrated ammonia *R*.

4.2. VOLUMETRIC ANALYSIS

01/2005:40201

4.2.1. PRIMARY STANDARDS FOR VOLUMETRIC SOLUTIONS

Primary standards for volumetric solutions are indicated by the suffix RV. Primary standards of suitable quality may be obtained from commercial sources or prepared by the following methods.

Benzoic acid. $C_7H_6O_2$. (M_r 122.1). 2000200. [65-85-0].
Sublime benzoic acid *R* in a suitable apparatus.

Potassium bromate. $KBrO_3$. (M_r 167.0). 2000300. [7758-01-2].
Crystallise potassium bromate *R* from boiling water *R*. Collect the crystals and dry to constant mass at 180 °C.

Potassium hydrogen phthalate. $C_8H_5KO_4$. (M_r 204.2). 2000400. [877-24-7].
Recrystallise potassium hydrogen phthalate *R* from boiling water *R*, collect the crystals at a temperature above 35 °C and dry to constant mass at 110 °C.

Sodium carbonate. Na_2CO_3 . (M_r 106.0). 2000500. [497-19-8].
Filter at room temperature a saturated solution of sodium carbonate *R*. Introduce slowly into the filtrate a stream of carbon dioxide *R* with constant cooling and stirring. After about 2 h, collect the precipitate on a sintered-glass filter. Wash the filter with iced water *R* containing carbon dioxide. After drying at 100 °C to 105 °C, heat to constant mass at 270 °C to 300 °C, stirring from time to time.

Sodium chloride. $NaCl$. (M_r 58.44). 2000600. [7647-14-5].
To 1 volume of a saturated solution of sodium chloride *R* add 2 volumes of hydrochloric acid *R*. Collect the crystals formed and wash with hydrochloric acid *R1*. Remove the hydrochloric acid by heating on a water-bath and dry the crystals to constant mass at 300 °C.

Sulphanilic acid. $C_6H_7NO_3S$. (M_r 173.2). 2000700. [121-57-3].
Recrystallise sulphanilic acid *R* from boiling water *R*. Filter and dry to constant mass at 100 °C to 105 °C.

Zinc. Zn . (M_r 65.4). 2000800. [7440-66-6].
Use a quality containing not less than 99.9 per cent of Zn.

01/2005:40202

4.2.2. VOLUMETRIC SOLUTIONS

Volumetric solutions are prepared according to the usual chemical analytical methods. The accuracy of the apparatus used is verified to ensure that it is appropriate for the intended use.

The concentration of volumetric solutions is indicated in terms of molarity. Molarity expresses, as the number of moles, the amount of substance dissolved in 1 litre of solution. A solution which contains x moles of substance per litre is said to be x M.

Volumetric solutions do not differ from the prescribed strength by more than 10 per cent. The molarity of the volumetric solutions is determined by an appropriate number of titrations. The repeatability does not exceed 0.2 per cent (relative standard deviation).

Volumetric solutions are standardised by the methods described below. When a volumetric solution is to be used in an assay in which the end-point is determined by an electrochemical process (for example, amperometry or potentiometry) the solution is standardised by the same method. The composition of the medium in which a volumetric solution is standardised should be the same as that in which it is to be used.

Solutions more dilute than those described are obtained by diluting the latter with carbon dioxide-free water *R*. The correction factors of these solutions are the same as those from which the dilutions were prepared.

0.1 M Acetic acid. 3008900.

Dilute 6.0 g of glacial acetic acid *R* to 1000.0 ml with water *R*.

Standardisation. To 25.0 ml of acetic acid add 0.5 ml of phenolphthalein solution *R* and titrate with 0.1 M sodium hydroxide.

0.1 M Ammonium and cerium nitrate. 3000100.

Shake for 2 min a solution containing 56 ml of sulphuric acid *R* and 54.82 g of ammonium and cerium nitrate *R*, add five successive quantities, each of 100 ml, of water *R*, shaking after each addition. Dilute the clear solution to 1000.0 ml with water *R*. Standardise the solution after 10 days.

Standardisation. To 25.0 ml of the ammonium and cerium nitrate solution add 2.0 g of potassium iodide *R* and 150 ml of water *R*. Titrate immediately with 0.1 M sodium thiosulphate, using 1 ml of starch solution *R* as indicator.
Storage: protected from light.

0.01 M Ammonium and cerium nitrate. 3000200.

To 100.0 ml of 0.1 M ammonium and cerium nitrate add, with cooling, 30 ml of sulphuric acid *R* and dilute to 1000.0 ml with water *R*.

0.1 M Ammonium and cerium sulphate. 3000300.

Dissolve 65.0 g of ammonium and cerium sulphate *R* in a mixture of 500 ml of water *R* and 30 ml of sulphuric acid *R*. Allow to cool and dilute to 1000.0 ml with water *R*.

Standardisation. To 25.0 ml of the ammonium and cerium sulphate solution add 2.0 g of potassium iodide *R* and 150 ml of water *R*. Titrate immediately with 0.1 M sodium thiosulphate, using 1 ml of starch solution *R* as indicator.

0.01 M Ammonium and cerium sulphate. 3000400.

To 100.0 ml of 0.1 M ammonium and cerium sulphate add, with cooling, 30 ml of sulphuric acid *R* and dilute to 1000.0 ml with water *R*.

0.1 M Ammonium thiocyanate. 3000500.

Dissolve 7.612 g of ammonium thiocyanate *R* in water *R* and dilute to 1000.0 ml with the same solvent.

Standardisation. To 20.0 ml of 0.1 M silver nitrate add 25 ml of water *R*, 2 ml of dilute nitric acid *R* and 2 ml of ferric ammonium sulphate solution *R2*. Titrate with the ammonium thiocyanate solution until a reddish-yellow colour is obtained.

0.1 M Barium chloride. 3000600.

Dissolve 24.4 g of *barium chloride R* in *water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. To 10.0 ml of the barium chloride solution add 60 ml of *water R*, 3 ml of *concentrated ammonia R* and 0.5 mg to 1 mg of *phthalein purple R*. Titrate with *0.1 M sodium edetate*. When the solution begins to decolorise, add 50 ml of *alcohol R* and continue the titration until the blue-violet colour disappears.

0.05 M Barium perchlorate. 3000700.

Dissolve 15.8 g of *barium hydroxide R* in a mixture of 7.5 ml of *perchloric acid R* and 75 ml of *water R*, adjust the solution to pH 3 by adding *perchloric acid R* and filter if necessary. Add 150 ml of *alcohol R* and dilute to 250 ml with *water R*. Dilute to 1000.0 ml with *buffer solution pH 3.7 R*.

Standardisation. To 5.0 ml of *0.05 M sulphuric acid* add 5 ml of *water R*, 50 ml of *buffer solution pH 3.7 R* and 0.5 ml of *alizarin s solution R*. Titrate with the barium perchlorate solution until an orange-red colour appears. Standardise immediately before use.

0.025 M Barium perchlorate. 3009600.

Dilute 500.0 ml of *0.05 M barium perchlorate* to 1000.0 ml with *buffer solution pH 3.7 R*.

0.004 M Benzethonium chloride. 3000900.

Dissolve in *water R* 1.792 g of *benzethonium chloride R*, previously dried to constant mass at 100 °C to 105 °C, and dilute to 1000.0 ml with the same solvent.

Standardisation. Calculate the molarity of the solution from the content of $C_{27}H_{42}ClNO_2$ in the dried benzethonium chloride determined as follows. Dissolve 0.350 g of the dried substance in 30 ml of *anhydrous acetic acid R* and add 6 ml of *mercuric acetate solution R*. Titrate with *0.1 M perchloric acid*, using 0.05 ml of *crystal violet solution R* as indicator. Carry out a blank titration.

1 ml of *0.1 M perchloric acid* is equivalent to 44.81 mg of $C_{27}H_{42}ClNO_2$.

0.0167 M Bromide-bromate. 3001000.

Dissolve 2.7835 g of *potassium bromate RV* and 13 g of *potassium bromide R* in *water R* and dilute to 1000.0 ml with the same solvent.

0.1 M Cerium sulphate. 3001100.

Dissolve 40.4 g of *cerium sulphate R* in a mixture of 500 ml of *water R* and 50 ml of *sulphuric acid R*. Allow to cool and dilute to 1000.0 ml with *water R*.

Standardisation. To 25.0 ml of the cerium sulphate solution, add 2.0 g of *potassium iodide R* and 150 ml of *water R*. Titrate immediately with *0.1 M sodium thiosulphate* using 1 ml of *starch solution R* as indicator.

0.02 M Copper sulphate. 3001200.

Dissolve 5.0 g of *copper sulphate R* in *water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. To 20.0 ml of the copper sulphate solution add 2 g of *sodium acetate R* and 0.1 ml of *pyridylazonaphthol solution R*. Titrate with *0.02 M sodium edetate* until the colour changes from violet-blue to bright green. Titrate slowly towards the end of the titration.

0.1 M Ferric ammonium sulphate. 3001300.

Dissolve 50.0 g of *ferric ammonium sulphate R* in a mixture of 6 ml of *sulphuric acid R* and 300 ml of *water R* and dilute to 1000.0 ml with *water R*.

Standardisation. To 25.0 ml of the ferric ammonium sulphate solution, add 3 ml of *hydrochloric acid R* and 2 g of *potassium iodide R*. Allow to stand for 10 min. Titrate with *0.1 M sodium thiosulphate*, using 1 ml of *starch solution R* as indicator.

1 ml of *0.1 M sodium thiosulphate* is equivalent to 48.22 mg of $FeNH_4(SO_4)_2 \cdot 12H_2O$.

0.1 M Ferrous sulphate. 3001400.

Dissolve 27.80 g of *ferrous sulphate R* in 500 ml of *dilute sulphuric acid R* and dilute to 1000.0 ml with *water R*.

Standardisation. To 25.0 ml of the ferrous sulphate solution add 3 ml of *phosphoric acid R* and titrate immediately with *0.02 M potassium permanganate*. Standardise immediately before use.

6 M Hydrochloric acid. 3001500.

Dilute 618.0 g of *hydrochloric acid R* to 1000.0 ml with *water R*.

3 M Hydrochloric acid. 3001600.

Dilute 309.0 g of *hydrochloric acid R* to 1000.0 ml with *water R*.

2 M Hydrochloric acid. 3001700.

Dilute 206.0 g of *hydrochloric acid R* to 1000.0 ml with *water R*.

1 M Hydrochloric acid. 3001800.

Dilute 103.0 g of *hydrochloric acid R* to 1000.0 ml with *water R*.

Standardisation. Dissolve 1.000 g of *sodium carbonate RV* in 50 ml of *water R*, add 0.1 ml of *methyl orange solution R* and titrate with the hydrochloric acid until the solution just becomes yellowish-red. Boil for 2 min. The solution reverts to yellow. Cool and continue the titration until a yellowish-red colour is obtained.

1 ml of *1 M hydrochloric acid* is equivalent to 53.00 mg of Na_2CO_3 .

0.1 M Hydrochloric acid. 3002100.

Dilute 100.0 ml of *1 M hydrochloric acid* to 1000.0 ml with *water R*.

Standardisation. Carry out the titration described for *1 M hydrochloric acid* using 0.100 g of *sodium carbonate RV* dissolved in 20 ml of *water R*.

1 ml of *0.1 M hydrochloric acid* is equivalent to 5.30 mg of Na_2CO_3 .

0.1 M Hydrochloric acid, alcoholic. 3008800.

Dilute 9.0 ml of *hydrochloric acid R* to 1000.0 ml with *aldehyde-free alcohol R*.

0.5 M Iodine. 3009400.

Dissolve 127 g of *iodine R* and 200 g of *potassium iodide R* in *water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. To 2.0 ml of the iodine solution add 1 ml of *dilute acetic acid R* and 50 ml of *water R*. Titrate with *0.1 M sodium thiosulphate*, using *starch solution R* as indicator.

Storage: protected from light.

0.05 M Iodine. 3002700.

Dissolve 12.7 g of *iodine R* and 20 g of *potassium iodide R* in *water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. To 20.0 ml of the iodine solution add 1 ml of *dilute acetic acid R* and 30 ml of *water R*. Titrate with *0.1 M sodium thiosulphate*, using *starch solution R* as indicator.

Storage: protected from light.

0.01 M Iodine. 3002900.

Add 0.3 g of *potassium iodide R* to 20.0 ml of 0.05 M iodine and dilute to 100.0 ml with *water R*.

0.1 M Lead nitrate. 3003100.

Dissolve 33 g of *lead nitrate R* in *water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. Take 20.0 ml of the lead nitrate solution and carry out the determination of lead by complexometry (2.5.11).

0.05 M Lead nitrate. 3009700.

Dilute 50.0 ml of 0.1 M *Lead nitrate* to 100.0 ml with *water R*.

0.1 M Lithium methoxide. 3003300.

Dissolve 0.694 g of *lithium R* in 150 ml of *anhydrous methanol R* and dilute to 1000.0 ml with *toluene R*.

Standardisation. To 10 ml of *dimethylformamide R* add 0.05 ml of a 3 g/l solution of *thymol blue R* in *methanol R* and titrate with the lithium methoxide solution until a pure blue colour is obtained. Immediately add 0.200 g of *benzoic acid RV*. Stir to effect solution and titrate with the lithium methoxide solution until the pure blue colour is again obtained. Protect the solution from atmospheric carbon dioxide throughout the titration. From the volume of titrant used in the second titration ascertain the exact strength of the lithium methoxide solution. Standardise immediately before use.

1 ml of 0.1 M *lithium methoxide* is equivalent to 12.21 mg of $C_7H_6O_2$.

0.1 M Magnesium chloride. 3003400.

Dissolve 20.33 g of *magnesium chloride R* in *water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. Carry out the determination of magnesium by complexometry (2.5.11).

1 M Nitric acid. 3003600.

Dilute 96.6 g of *nitric acid R* to 1000.0 ml with *water R*.

Standardisation. Dissolve 1.000 g of *sodium carbonate RV* in 50 ml of *water R*, add 0.1 ml of *methyl orange solution R* and titrate with the nitric acid until the solution just becomes reddish-yellow; boil for 2 min. The solution reverts to yellow. Cool and continue the titration until a reddish-yellow colour is obtained.

1 ml of 1 M *nitric acid* is equivalent to 53.00 mg of Na_2CO_3 .

0.1 M Perchloric acid. 3003900.

Place 8.5 ml of *perchloric acid R* in a volumetric flask containing about 900 ml of *glacial acetic acid R* and mix. Add 30 ml of *acetic anhydride R*, dilute to 1000.0 ml with *glacial acetic acid R*, mix and allow to stand for 24 h. Determine the water content (2.5.12) without addition of *methanol* and, if necessary, adjust the water content to between 0.1 per cent and 0.2 per cent by adding either *acetic anhydride R* or *water R*. Allow to stand for 24 h.

Standardisation. Dissolve 0.350 g of *potassium hydrogen phthalate RV* in 50 ml of *anhydrous acetic acid R*, warming gently if necessary. Allow to cool protected from the air, and titrate with the perchloric acid solution, using 0.05 ml of *crystal violet solution R* as indicator. Note the temperature of the perchloric acid solution at the time of the titration. If the temperature at which an assay is carried out is different from that at which the *perchloric acid R* has been standardised the volume used in the assay becomes:

$$V_c = V [1 + (t_1 - t_2) 0.0011]$$

where t_1 is the temperature during standardisation, and t_2 is the temperature during the assay, V_c is the corrected volume and V the observed volume.

1 ml of 0.1 M *perchloric acid* is equivalent to 20.42 mg of $C_8H_5KO_4$.

0.05 M Perchloric acid. 3004000.

Dilute 50.0 ml of 0.1 M *perchloric acid* to 100.0 ml with *anhydrous acetic acid R*.

0.033 M Potassium bromate. 3004200.

Dissolve 5.5670 g of *potassium bromate RV* in *water R* and dilute to 1000.0 ml with the same solvent.

0.02 M Potassium bromate. 3004300.

Dissolve 3.340 g of *potassium bromate RV* in *water R* and dilute to 1000.0 ml with the same solvent.

0.0167 M Potassium bromate. 3004400.

Prepare by diluting 0.033 M *Potassium bromate*.

0.0083 M Potassium bromate. 3004500.

Prepare by diluting 0.033 M *Potassium bromate*.

0.0167 M Potassium dichromate. 3004600.

Dissolve 4.90 g of *potassium dichromate R* in *water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. To 20.0 ml of the potassium dichromate solution add 1 g of *potassium iodide R* and 7 ml of *dilute hydrochloric acid R*. Add 250 ml of *water R* and titrate with 0.1 M *sodium thiosulphate*, using 3 ml of *starch solution R* as indicator, until the colour changes from blue to light green.

0.1 M Potassium hydrogen phthalate. 3004700.

In a conical flask containing about 800 ml of *anhydrous acetic acid R*, dissolve 20.42 g of *potassium hydrogen phthalate RV*. Heat on a water-bath until completely dissolved, protected from humidity. Cool to 20 °C and dilute to 1000.0 ml with *anhydrous acetic acid R*.

1 M Potassium hydroxide. 3009100.

Dissolve 60 g of *potassium hydroxide R* in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. Titrate 20.0 ml of the potassium hydroxide solution with 1 M *hydrochloric acid*, using 0.5 ml of *phenolphthalein solution R* as indicator.

0.1 M Potassium hydroxide. 3004800.

Dissolve 6 g of *potassium hydroxide R* in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. Titrate 20.0 ml of the potassium hydroxide solution with 0.1 M *hydrochloric acid*, using 0.5 ml of *phenolphthalein solution R* as indicator.

0.5 M Potassium hydroxide in alcohol (60 per cent V/V). 3004900.

Dissolve 3 g of *potassium hydroxide R* in *aldehyde-free alcohol R* (60 per cent V/V) and dilute to 100.0 ml with the same solvent.

Standardisation. Titrate 20.0 ml of the alcoholic potassium hydroxide solution (60 per cent V/V) with 0.5 M *hydrochloric acid*, using 0.5 ml of *phenolphthalein solution R* as indicator.

0.5 M Potassium hydroxide, alcoholic. 3005000.

Dissolve 3 g of *potassium hydroxide R* in 5 ml of *water R* and dilute to 100.0 ml with *aldehyde-free alcohol R*.

Standardisation. Titrate 20.0 ml of the alcoholic potassium hydroxide solution with 0.5 M hydrochloric acid, using 0.5 ml of phenolphthalein solution R as indicator.

0.1 M Potassium hydroxide, alcoholic. 3005100.

Dilute 20.0 ml of 0.5 M alcoholic potassium hydroxide to 100.0 ml with aldehyde-free alcohol R.

0.01 M Potassium hydroxide, alcoholic. 3009000.

Dilute 2.0 ml of 0.5 M alcoholic potassium hydroxide to 100.0 ml with aldehyde-free alcohol R.

0.05 M Potassium iodate. 3005200.

Dissolve 10.70 g of potassium iodate R in water R and dilute to 1000.0 ml with the same solvent.

Standardisation. Dilute 25.0 ml of the potassium iodate solution to 100.0 ml with water R. To 20.0 ml of this solution add 2 g of potassium iodide R and 10 ml of dilute sulphuric acid R. Titrate with 0.1 M sodium thiosulphate, using 1 ml of starch solution R, added towards the end of the titration, as indicator.

0.001 M Potassium iodide. 3009200.

Dilute 10.0 ml of potassium iodide solution R (166 g/l) to 100.0 ml with water R. Dilute 5.0 ml of this solution to 500.0 ml with water R.

0.02 M Potassium permanganate. 3005300.

Dissolve 3.2 g of potassium permanganate R in water R and dilute to 1000.0 ml with the same solvent. Heat the solution for 1 h on a water-bath, allow to cool and filter through a sintered-glass filter.

Standardisation. To 20.0 ml of the potassium permanganate solution, add 2 g of potassium iodide R and 10 ml of dilute sulphuric acid R. Titrate with 0.1 M sodium thiosulphate, using 1 ml of starch solution R, added towards the end of the titration, as indicator. Standardise immediately before use.

Storage: protected from light.

0.1 M Silver nitrate. 3005600.

Dissolve 17.0 g of silver nitrate R in water R and dilute to 1000.0 ml with the same solvent.

Standardisation. Dissolve 0.100 g of sodium chloride RV in 30 ml of water R. Titrate with the silver nitrate solution, determining the end-point potentiometrically (2.2.20).

1 ml of 0.1 M silver nitrate is equivalent to 5.844 mg of NaCl.

Storage: protected from light.

0.001 M Silver nitrate. 3009300.

Dilute 5.0 ml of silver nitrate 0.1 M to 500.0 ml with water R.

0.1 M Sodium edetate. 3005900.

Dissolve 37.5 g of sodium edetate R in 500 ml of water R, add 100 ml of 1 M sodium hydroxide and dilute to 1000.0 ml with water R.

Standardisation. Dissolve 0.120 g of zinc RV in 4 ml of hydrochloric acid R1 and add 0.1 ml of bromine water R. Drive off the excess of bromine by boiling, add dilute sodium hydroxide solution R until the solution is weakly acid or neutral and carry out the assay of zinc by complexometry (2.5.11).

1 ml of 0.1 M sodium edetate is equivalent to 6.54 mg of Zn.

Storage: in a polyethylene container.

0.02 M Sodium edetate. 3006000.

Dissolve 7.444 g of sodium edetate R in water R and dilute to 1000.0 ml with the same solvent.

Standardisation. Dissolve 0.100 g of zinc RV in 4 ml of hydrochloric acid R1 and add 0.1 ml of bromine water R. Drive off the excess of bromine by boiling. Transfer the solution to a volumetric flask and dilute to 100.0 ml with water R. Transfer 25.0 ml of the solution to a 500 ml conical flask and dilute to 200 ml with water R. Add about 50 mg of xylene orange triturate R and hexamethylenetetramine R until the solution becomes violet-pink. Add 2 g of hexamethylenetetramine R in excess. Titrate with the sodium edetate solution until the violet-pink colour changes to yellow.

1 ml of 0.02 M sodium edetate is equivalent to 1.308 mg of Zn.

1 M Sodium hydroxide. 3006300.

Dissolve 42 g of sodium hydroxide R in carbon dioxide-free water R and dilute to 1000.0 ml with the same solvent.

Standardisation. Titrate 20.0 ml of the sodium hydroxide solution with 1 M hydrochloric acid using the indicator prescribed in the assay in which 1 M sodium hydroxide is used.

If sodium hydroxide free from carbonate is prescribed, prepare it as follows. Dissolve sodium hydroxide R in water R to give a concentration of 400 g/l to 600 g/l and allow to stand. Decant the clear supernatant liquid, taking precautions to avoid the introduction of carbon dioxide, and dilute with carbon dioxide-free water R to the required molarity. The solution complies with the following test. Titrate 20.0 ml of hydrochloric acid of the same molarity with the solution of sodium hydroxide, using 0.5 ml of phenolphthalein solution R as indicator. At the end-point add just sufficient of the acid to discharge the pink colour and concentrate the solution to 20 ml by boiling. During boiling add just sufficient acid to discharge the pink colour, which should not reappear after prolonged boiling. The volume of acid used does not exceed 0.1 ml.

0.1 M Sodium hydroxide. 3006600.

Dilute 100.0 ml of 1 M sodium hydroxide to 1000.0 ml with carbon dioxide-free water R.

Standardisation. Titrate 20.0 ml of the sodium hydroxide solution with 0.1 M hydrochloric acid, using the end-point detection prescribed for the assay in which the 0.1 M sodium hydroxide is used.

Standardisation (for use in the assay of halide salts of organic bases). Dissolve 0.100 g of benzoic acid RV in a mixture of 5 ml of 0.01 M hydrochloric acid and 50 ml of alcohol R. Carry out the titration (2.2.20), using the sodium hydroxide solution. Note the volume added between the 2 points of inflexion.

1 ml of 0.1 M sodium hydroxide is equivalent to 12.21 mg of $C_7H_6O_2$.

2 M Sodium hydroxide. 3009800.

Dissolve 84 g of sodium hydroxide R in carbon dioxide-free water R and dilute to 1000.0 ml with the same solvent.

0.1 M Sodium hydroxide, ethanolic. 3007000.

To 250 ml of ethanol R add 3.3 g of strong sodium hydroxide solution R.

Standardisation. Dissolve 0.100 g of benzoic acid RV in 2 ml of water R and 10 ml of alcohol R. Titrate with the ethanolic sodium hydroxide solution, using 0.2 ml of thymolphthalein solution R as indicator. Standardise immediately before use.

1 ml of 0.1 M ethanolic sodium hydroxide is equivalent to 12.21 mg of $C_7H_6O_2$.

0.1 M Sodium methoxide. 3007100.

Cool 175 ml of *anhydrous methanol R* in iced *water R* and add, in small portions, about 2.5 g of freshly cut *sodium R*. When the metal has dissolved, dilute to 1000.0 ml with *toluene R*.

Standardisation. To 10 ml of *dimethylformamide R* add 0.05 ml of a 3 g/l solution of *thymol blue R* in *methanol R*, and titrate with the sodium methoxide solution until a pure blue colour is obtained. Immediately add 0.200 g of *benzoic acid RV*. Stir to effect solution and titrate with the sodium methoxide solution until the pure blue colour is again obtained. Protect the solution from atmospheric carbon dioxide throughout the titration. From the volume of titrant used in the second titration ascertain the exact strength of the sodium methoxide solution. Standardise immediately before use.

1 ml of 0.1 M sodium methoxide is equivalent to 12.21 mg of $C_7H_6O_2$.

0.1 M Sodium nitrite. 3007200.

Dissolve 7.5 g of *sodium nitrite R* in *water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. Dissolve 0.300 g of *sulphanilic acid RV* in 50 ml of *dilute hydrochloric acid R* and carry out the determination of primary aromatic amino-nitrogen (2.5.8), using the sodium nitrite solution and determining the end-point electrometrically. Standardise immediately before use.

1 ml of 0.1 M sodium nitrite is equivalent to 17.32 mg of $C_6H_7NO_3S$.

0.1 M Sodium periodate. 3009500.

Dissolve 21.4 g of *sodium periodate R* in about 500 ml of *water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. In a stoppered flask, introduce 20.0 ml of the sodium periodate solution and add 5 ml of *perchloric acid R*. Close the flask and shake. Adjust the solution to pH 6.4 (2.2.3) using a saturated solution of *sodium hydrogen carbonate R*. Add 10 ml of *potassium iodide solution R*, close, shake and allow to stand for 2 min. Titrate with 0.025 M sodium arsenite until the yellow colour almost disappears. Add 2 ml of *starch solution R* and titrate slowly until the colour is completely discharged.

0.1 M Sodium thiosulphate. 3007300.

Dissolve 25 g of *sodium thiosulphate R* and 0.2 g of *sodium carbonate R* in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. To 10.0 ml of 0.033 M *potassium bromate*, add 40 ml of *water R*, 10 ml of *potassium iodide solution R* and 5 ml of *hydrochloric acid R1*. Titrate with the sodium thiosulphate solution, using 1 ml of *starch solution R*, added towards the end of the titration, as indicator.

0.5 M Sulphuric acid. 3007800.

Dissolve 28 ml of sulphuric acid R in *water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. Dissolve 1.000 g of *sodium carbonate RV* in 50 ml of *water R*, add 0.1 ml of *methyl orange solution R*, and titrate with the sulphuric acid until the solution begins

to turn reddish-yellow. Boil for about 2 min. The colour of the solutions reverts to yellow. Cool and titrate again until the reddish-yellow colour reappears.

1 ml of 0.5 M sulphuric acid is equivalent to 53.00 mg of Na_2CO_3 .

0.05 M Sulphuric acid. 3008000.

Dilute 100.0 ml of 0.5 M sulphuric acid to 1000.0 ml with *water R*.

Standardisation. Carry out the titration described for 0.5 M sulphuric acid, using 0.100 g of *sodium carbonate RV*, dissolved in 20 ml of *water R*.

1 ml of 0.05 M sulphuric acid is equivalent to 5.30 mg of Na_2CO_3 .

0.1 M Tetrabutylammonium hydroxide. 3008300.

Dissolve 40 g of *tetrabutylammonium iodide R* in 90 ml of *anhydrous methanol R*, add 20 g of finely powdered *silver oxide R* and shake vigorously for 1 h. Centrifuge a few millilitres of the mixture and test the supernatant liquid for iodides. If a positive reaction is obtained, add an additional 2 g of *silver oxide R* and shake for a further 30 min. Repeat this procedure until the liquid is free from iodides, filter the mixture through a fine sintered-glass filter and rinse the reaction vessel and filter with three quantities, each of 50 ml, of *toluene R*. Add the washings to the filtrate and dilute to 1000.0 ml with *toluene R*. Pass dry carbon dioxide-free nitrogen through the solution for 5 min.

Standardisation. To 10 ml of *dimethylformamide R* add 0.05 ml of a 3 g/l solution of *thymol blue R* in *methanol R* and titrate with the tetrabutylammonium hydroxide solution until a pure blue colour is obtained. Immediately add 0.200 g of *benzoic acid RV*. Stir to effect solution, and titrate with the tetrabutylammonium hydroxide solution until the pure blue colour is again obtained. Protect the solution from atmospheric carbon dioxide throughout the titration. From the volume of titrant used in the second titration ascertain the exact strength of the tetrabutylammonium hydroxide solution. Standardise immediately before use.

1 ml of 0.1 M tetrabutylammonium hydroxide is equivalent to 12.21 mg of $C_7H_6O_2$.

0.1 M Tetrabutylammonium hydroxide in 2-propanol. 3008400.

Prepare as described for 0.1 M tetrabutylammonium hydroxide using 2-propanol R instead of *toluene R* and standardise as described.

0.05 M Zinc chloride. 3008500.

Dissolve 6.82 g of *zinc chloride R*, weighed with appropriate precautions, in *water R*. If necessary, add dropwise *dilute hydrochloric acid R* until the opalescence disappears. Dilute to 1000.0 ml with *water R*.

Standardisation. To 20.0 ml of the zinc chloride solution add 5 ml of *dilute acetic acid R* and carry out the determination of zinc by complexometry (2.5.11).

0.1 M Zinc sulphate. 3008600.

Dissolve 29 g of *zinc sulphate R* in *water R* and dilute to 1000.0 ml with the same solvent.

Standardisation. To 20.0 ml of the zinc sulphate solution add 5 ml of *dilute acetic acid R* and carry out the determination of zinc by complexometry (2.5.11).

5.1. GENERAL TEXTS ON STERILITY

01/2005:50101

5.1.1. METHODS OF PREPARATION OF STERILE PRODUCTS

Sterility is the absence of viable micro-organisms. The sterility of a product cannot be guaranteed by testing; it has to be assured by the application of a suitably validated production process. It is essential that the effect of the chosen sterilisation procedure on the product (including its final container or package) is investigated to ensure effectiveness and the integrity of the product and that the procedure is validated before being applied in practice. It is recommended that the choice of the container is such as to allow the optimum sterilisation to be applied. Failure to follow meticulously a validated process involves the risk of a non-sterile product or of a deteriorated product. Revalidation is carried out whenever major changes in the sterilisation procedure, including changes in the load, take place. It is expected that the principles of good manufacturing practice (as described in, for example, the European Community Guide to GMP) will have been observed in the design of the process including, in particular, the use of:

- qualified personnel with appropriate training,
- adequate premises,
- suitable production equipment, designed for easy cleaning and sterilisation,
- adequate precautions to minimise the bioburden prior to sterilisation,
- validated procedures for all critical production steps,
- environmental monitoring and in-process testing procedures.

The precautions necessary to minimise the pre-sterilisation bioburden include the use of components with an acceptable low degree of microbial contamination. Microbiological monitoring and setting of suitable action limits may be advisable for ingredients which are liable to be contaminated because of their origin, nature or method of preparation.

The methods described here apply mainly to the inactivation or removal of bacteria, yeasts and moulds. For biological products of animal or human origin or in cases where such material has been used in the production process, it is necessary during validation to demonstrate that the process is capable of the removal or inactivation of relevant viral contamination. Guidance on this aspect is provided in, for example, the appropriate European Community Notes for Guidance.

Wherever possible, a process in which the product is sterilised in its final container (terminal sterilisation) is chosen. When a fully validated terminal sterilisation method by steam, dry heat or ionising radiation is used, parametric release, that is the release of a batch of sterilised items based on process data rather than on the basis of submitting a sample of the items to sterility testing, may be carried out, subject to the approval of the competent authority.

If terminal sterilisation is not possible, filtration through a bacteria-retentive filter or aseptic processing is used; wherever possible, appropriate additional treatment of the product (for example, heating of the product) in its final container is applied. In all cases, the container and closure are required to maintain the sterility of the product throughout its shelf-life.

Sterility Assurance Level (SAL)

Where appropriate reference is made within the methods described below, to a “sterility assurance level” or “SAL”. The achievement of sterility within any one item in a population of items submitted to a sterilisation process cannot be guaranteed nor can it be demonstrated. The inactivation of micro-organisms by physical or chemical means follows an exponential law; thus there is always a finite statistical probability that a micro-organism may survive the sterilising process. For a given process, the probability of survival is determined by the number, types and resistance of the micro-organisms present and by the environment in which the organisms exist during treatment. The SAL of a sterilising process is the degree of assurance with which the process in question renders a population of items sterile. The SAL for a given process is expressed as the probability of a non-sterile item in that population. An SAL of 10^{-6} , for example, denotes a probability of not more than one viable micro-organism in 1×10^6 sterilised items of the final product. The SAL of a process for a given product is established by appropriate validation studies.

METHODS AND CONDITIONS OF STERILISATION

Sterilisation may be carried out by one of the methods described below. Modifications to, or combinations of, these methods may be used provided that the chosen procedure is validated both with respect to its effectiveness and the integrity of the product including its container or package. For all methods of sterilisation the critical conditions of the operation are monitored in order to confirm that the previously determined required conditions are achieved throughout the batch during the whole sterilisation process. This applies in all cases including those where the reference conditions are used.

TERMINAL STERILISATION

For terminal sterilisation it is essential to take into account the non-uniformity of the physical and, where relevant, chemical conditions within the sterilising chamber. The location within the sterilising chamber that is least accessible to the sterilising agent is determined for each loading configuration of each type and size of container or package (for example, the coolest location in an autoclave). The minimum lethality delivered by the sterilising cycle and the reproducibility of the cycle are also determined in order to ensure that all loads will consistently receive the specified treatment.

Having established a terminal sterilisation process, knowledge of its performance in routine use is gained wherever possible, by monitoring and suitably recording the physical and, where relevant, chemical conditions achieved within the load in the chamber throughout each sterilising cycle.

Steam sterilisation (Heating in an autoclave). Sterilisation by saturated steam under pressure is preferred, wherever applicable, especially for aqueous preparations. For this method of terminal sterilisation the reference conditions for aqueous preparations are heating at a minimum of 121°C for 15 min. Other combinations of time and temperature may be used provided that it has been satisfactorily demonstrated that the process chosen delivers an adequate and reproducible level of lethality when operating routinely within the established tolerances. The procedures and precautions employed are such, as to give an SAL of 10^{-6} or better. Guidance concerning validation by means of the F_0 concept is provided below (5.1.5).

Knowledge of the physical conditions (temperature and pressure) within the autoclave chamber during the sterilisation procedure is obtained. The temperature is

usually measured by means of temperature-sensing elements inserted into representative containers together with additional elements at the previously established coolest part of the loaded chamber. The conditions throughout each cycle are suitably recorded, for example, as a temperature-time chart, or by any other suitable means.

Where a biological assessment is carried out, this is obtained using a suitable biological indicator (5.1.2).

Dry heat sterilisation. For this method of terminal sterilisation the reference conditions are a minimum of 160 °C for at least 2 h. Other combinations of time and temperature may be used provided that it has been satisfactorily demonstrated that the process chosen delivers an adequate and reproducible level of lethality when operated routinely within the established tolerances. The procedures and precautions employed are such as to give an SAL of 10^{-6} or better.

Dry heat sterilisation is carried out in an oven equipped with forced air circulation or other equipment specially designed for the purpose. The steriliser is loaded in such a way that a uniform temperature is achieved throughout the load. Knowledge of the temperature within the steriliser during the sterilisation procedure is usually obtained by means of temperature-sensing elements inserted into representative containers together with additional elements at the previously established coolest part of the loaded steriliser. The temperature throughout each cycle is suitably recorded.

Where a biological assessment is carried out, this is obtained using a suitable biological indicator (5.1.2).

Dry heat at temperatures greater than 220 °C is frequently used for sterilisation and depyrogenation of glassware. In this case demonstration of a 3-log reduction in heat resistant endotoxin can be used as a replacement for biological indicators (5.1.2).

Ionising radiation sterilisation. Sterilisation by this method is achieved by exposure of the product to ionising radiation in the form of gamma radiation from a suitable radioisotopic source (such as cobalt 60) or of a beam of electrons energised by a suitable electron accelerator.

In some countries there are regulations that lay down rules for the use of ionising radiation for sterilisation purposes, for example, in the appropriate European Community Notes for Guidance.

For this method of terminal sterilisation the reference absorbed dose is 25 kGy. Other doses may be used provided that it has satisfactorily been demonstrated that the dose chosen delivers an adequate and reproducible level of lethality when the process is operated routinely within the established tolerances. The procedures and precautions employed are such as to give an SAL of 10^{-6} or better.

During the sterilisation procedure the radiation absorbed by the product is monitored regularly by means of established dosimetry procedures that are independent of dose rate. Dosimeters are calibrated against a standard source at a reference radiation plant on receipt from the supplier and at suitable intervals of not longer than one year thereafter.

Where a biological assessment is carried out, this is obtained using a suitable biological indicator (5.1.2).

Gas sterilisation. This method of sterilisation is only to be used where there is no suitable alternative. It is essential that penetration by gas and moisture into the material to be sterilised is ensured and that it is followed by a process of elimination of the gas under conditions that have been previously established to ensure that any residue of gas or its transformation products in the sterilised product is below the concentration that could give rise to toxic effects during

use of the product. Guidance on this aspect with respect to the use of ethylene oxide is provided, for example, in the appropriate European Community Notes for Guidance.

Wherever possible, the gas concentration, relative humidity, temperature and duration of the process are measured and recorded. Measurements are made where sterilisation conditions are least likely to be achieved, as determined at validation.

The effectiveness of the process applied to each sterilisation load is checked using a suitable biological indicator (5.1.2).

A suitable sample of each batch is tested for sterility (2.6.1) before the batch is released.

FILTRATION

Certain active ingredients and products that cannot be terminally sterilised may be subjected to a filtration procedure using a filter of a type that has been demonstrated to be satisfactory by means of a microbial challenge test using a suitable test micro-organism. A suspension of *Pseudomonas diminuta* (ATCC 19146, NCIMB 11091 or CIP 103020) may be suitable. It is recommended that a challenge of at least 10^7 CFU per cm² of active filter surface is used and that the suspension is prepared in tryptone soya broth which, after passage through the filter, is collected aseptically and incubated aerobically at 32 °C. Such products need special precautions. The production process and environment are designed to minimise microbial contamination and are regularly subjected to appropriate monitoring procedures. The equipment, containers and closures and, wherever possible, the ingredients are subjected to an appropriate sterilisation process. It is recommended that the filtration process is carried out as close as possible to the filling point. The operations following filtration are carried out under aseptic conditions.

Solutions are passed through a bacteria-retentive membrane with a nominal pore size of 0.22 µm or less or any other type of filter known to have equivalent properties of bacteria retention. Appropriate measures are taken to avoid loss of solute by adsorption on to the filter and to avoid the release of contaminants from the filter. Attention is given to the bioburden prior to filtration, filter capacity, batch size and duration of filtration. The filter is not used for a longer period than has been approved by validation of the combination of the filter and the product in question.

The integrity of an assembled sterilising filter is verified before use and confirmed after use by carrying out tests appropriate to the type of filter used and the stage of testing, for example bubble-point, pressure hold or diffusion rate tests.

Due to the potential additional risks of the filtration method as compared with other sterilisation processes, a prefiltration through a bacteria-retentive filter may be advisable in cases where a low bioburden cannot be ensured by other means.

ASEPTIC PREPARATION

The objective of aseptic processing is to maintain the sterility of a product that is assembled from components, each of which has been sterilised by one of the above methods. This is achieved by using conditions and facilities designed to prevent microbial contamination. Aseptic processing may include aseptic filling of products into container/closure systems, aseptic blending of formulations followed by aseptic filling and aseptic packaging.

In order to maintain the sterility of the components and the product during processing, careful attention needs to be given to:

- environment,
- personnel,

- critical surfaces,
- container/closure sterilisation and transfer procedures,
- maximum holding period of the product before filling into the final container.

Process validation includes appropriate checks on all the above and checks on the process are regularly carried out by means of process simulation tests using microbial growth media which are then incubated and examined for microbial contamination (media fill tests). In addition, a suitable sample of each batch of any product that is sterilised by filtration and/or aseptically processed is tested for sterility (2.6.1) before the batch is released.

01/2005:50102

5.1.2. BIOLOGICAL INDICATORS OF STERILISATION

Biological indicators are standardised preparations of selected micro-organisms used to assess the effectiveness of a sterilisation procedure. They usually consist of a population of bacterial spores placed on an inert carrier, for example a strip of filter paper, a glass slide or a plastic tube. The inoculated carrier is covered in such a way that it is protected from any deterioration or contamination, while allowing the sterilising agent to enter into contact with the micro-organisms. Spore suspensions may be presented in sealed ampoules. Biological indicators are prepared in such a way that they can be stored under defined conditions; an expiry date is set.

Micro-organisms of the same bacterial species as the bacteria used to manufacture the biological indicators may be inoculated directly into a liquid product to be sterilised or into a liquid product similar to that to be sterilised. In this case, it must be demonstrated that the liquid product has no inhibiting effect on the spores used, especially as regards their germination.

A biological indicator is characterised by the name of the species of bacterium used as the reference micro-organism, the number of the strain in the original collection, the number of viable spores per carrier and the *D*-value. The *D*-value is the value of a parameter of sterilisation (duration or absorbed dose) required to reduce the number of viable organisms to 10 per cent of the original number. It is of significance only under precisely defined experimental conditions. Only the stated micro-organisms are present. Biological indicators consisting of more than one species of bacteria on the same carrier may be used. Information on the culture medium and the incubation conditions is supplied.

It is recommended that the indicator organisms are placed at the locations presumed, or wherever possible, found by previous physical measurement to be least accessible to the sterilising agent. After exposure to the sterilising agent, aseptic technique is used to transfer carriers of spores to the culture media, so that no contamination is present at the time of examination. Biological indicators that include an ampoule of culture medium placed directly in the packaging protecting the inoculated carrier may be used.

A choice of indicator organisms is made such that:

- a) the resistance of the test strain to the particular sterilisation method is great compared to the resistance of all pathogenic micro-organisms and to that of micro-organisms potentially contaminating the product,
- b) the test strain is non-pathogenic,
- c) the test strain is easy to culture.

After incubation, growth of the reference micro-organisms subjected to a sterilisation procedure demonstrates that the procedure has been unsatisfactory.

Steam sterilisation. The use of biological indicators intended for steam sterilisation is recommended for the validation of sterilisation cycles. Spores of *Bacillus stearothermophilus* (for example, ATCC 7953, NCTC 10007, NCIMB 8157 or CIP 52.81) are recommended. The number of viable spores exceeds 5×10^5 per carrier. The *D*-value at 121 °C exceeds 1.5 min. It is verified that exposing the biological indicators to steam at 121 ± 1 °C for 6 min leaves revivable spores, and that there is no growth of the reference micro-organisms after the biological indicators have been exposed to steam at 121 ± 1 °C for 15 min.

Dry-heat sterilisation. Spores of *Bacillus subtilis* (for example, var. *niger* ATCC 9372, NCIMB 8058 or CIP 77.18) are recommended for the preparation of biological indicators. The number of viable spores exceeds 1×10^5 per carrier and the *D*-value at 160 °C is approximately 1 min to 3 min. Dry heat at temperatures greater than 220 °C is frequently used for sterilisation and depyrogenation of glassware. In this case, demonstration of a 3 log reduction in heat resistant bacterial endotoxin can be used as a replacement for biological indicators.

Ionising radiation sterilisation. Biological indicators may be used to monitor routine operations, as an additional possibility to assess the effectiveness of the set dose of radiation energy, especially in the case of accelerated electron sterilisation. The spores of *Bacillus pumilus* (for example, ATCC 27.142, NCTC 10327, NCIMB 10692 or CIP 77.25) are recommended. The number of viable spores exceeds 1×10^7 per carrier. The *D*-value exceeds 1.9 kGy. It is verified that there is no growth of the reference micro-organisms after the biological indicators have been exposed to 25 kGy (*minimum absorbed dose*).

Gas sterilisation. The use of biological indicators is necessary for all gas sterilisation procedures, both for the validation of the cycles and for routine operations. Gas sterilisation is widely used for medical devices, isolators, chambers, etc. Use for such purposes is outside the scope of the European Pharmacopoeia. The use of spores of *Bacillus subtilis* (for example, var. *niger* ATCC 9372, NCIMB 8058 or CIP 77.18) is recommended for ethylene oxide. The number of viable spores exceeds 5×10^5 per carrier. The parameters of resistance are the following: the *D*-value exceeds 2.5 min for a test cycle involving 600 mg/l of ethylene oxide, at 54 °C and at 60 per cent relative humidity. It is verified that there is no growth of the reference micro-organisms after the biological indicators have been exposed to the test cycle described above for 60 min and that exposing the indicators to a reduced temperature cycle (600 mg/l, 30 °C and 60 per cent relative humidity) for 15 min leaves revivable spores. Exposing the indicators to 600 mg/l of ethylene oxide at 54 °C for 60 min without humidification must leave revivable spores to ensure that the biological indicator is able to reveal insufficient humidification.

01/2005:50103

5.1.3. EFFICACY OF ANTIMICROBIAL PRESERVATION

If a pharmaceutical preparation does not itself have adequate antimicrobial activity, antimicrobial preservatives may be added, particularly to aqueous preparations, to prevent proliferation or to limit microbial contamination which, during normal conditions of storage and use, particularly for multidose containers, could occur in a product and present

- critical surfaces,
- container/closure sterilisation and transfer procedures,
- maximum holding period of the product before filling into the final container.

Process validation includes appropriate checks on all the above and checks on the process are regularly carried out by means of process simulation tests using microbial growth media which are then incubated and examined for microbial contamination (media fill tests). In addition, a suitable sample of each batch of any product that is sterilised by filtration and/or aseptically processed is tested for sterility (2.6.1) before the batch is released.

01/2005:50102

5.1.2. BIOLOGICAL INDICATORS OF STERILISATION

Biological indicators are standardised preparations of selected micro-organisms used to assess the effectiveness of a sterilisation procedure. They usually consist of a population of bacterial spores placed on an inert carrier, for example a strip of filter paper, a glass slide or a plastic tube. The inoculated carrier is covered in such a way that it is protected from any deterioration or contamination, while allowing the sterilising agent to enter into contact with the micro-organisms. Spore suspensions may be presented in sealed ampoules. Biological indicators are prepared in such a way that they can be stored under defined conditions; an expiry date is set.

Micro-organisms of the same bacterial species as the bacteria used to manufacture the biological indicators may be inoculated directly into a liquid product to be sterilised or into a liquid product similar to that to be sterilised. In this case, it must be demonstrated that the liquid product has no inhibiting effect on the spores used, especially as regards their germination.

A biological indicator is characterised by the name of the species of bacterium used as the reference micro-organism, the number of the strain in the original collection, the number of viable spores per carrier and the *D*-value. The *D*-value is the value of a parameter of sterilisation (duration or absorbed dose) required to reduce the number of viable organisms to 10 per cent of the original number. It is of significance only under precisely defined experimental conditions. Only the stated micro-organisms are present. Biological indicators consisting of more than one species of bacteria on the same carrier may be used. Information on the culture medium and the incubation conditions is supplied.

It is recommended that the indicator organisms are placed at the locations presumed, or wherever possible, found by previous physical measurement to be least accessible to the sterilising agent. After exposure to the sterilising agent, aseptic technique is used to transfer carriers of spores to the culture media, so that no contamination is present at the time of examination. Biological indicators that include an ampoule of culture medium placed directly in the packaging protecting the inoculated carrier may be used.

A choice of indicator organisms is made such that:

- a) the resistance of the test strain to the particular sterilisation method is great compared to the resistance of all pathogenic micro-organisms and to that of micro-organisms potentially contaminating the product,
- b) the test strain is non-pathogenic,
- c) the test strain is easy to culture.

After incubation, growth of the reference micro-organisms subjected to a sterilisation procedure demonstrates that the procedure has been unsatisfactory.

Steam sterilisation. The use of biological indicators intended for steam sterilisation is recommended for the validation of sterilisation cycles. Spores of *Bacillus stearothermophilus* (for example, ATCC 7953, NCTC 10007, NCIMB 8157 or CIP 52.81) are recommended. The number of viable spores exceeds 5×10^5 per carrier. The *D*-value at 121 °C exceeds 1.5 min. It is verified that exposing the biological indicators to steam at 121 ± 1 °C for 6 min leaves revivable spores, and that there is no growth of the reference micro-organisms after the biological indicators have been exposed to steam at 121 ± 1 °C for 15 min.

Dry-heat sterilisation. Spores of *Bacillus subtilis* (for example, var. *niger* ATCC 9372, NCIMB 8058 or CIP 77.18) are recommended for the preparation of biological indicators. The number of viable spores exceeds 1×10^5 per carrier and the *D*-value at 160 °C is approximately 1 min to 3 min. Dry heat at temperatures greater than 220 °C is frequently used for sterilisation and depyrogenation of glassware. In this case, demonstration of a 3 log reduction in heat resistant bacterial endotoxin can be used as a replacement for biological indicators.

Ionising radiation sterilisation. Biological indicators may be used to monitor routine operations, as an additional possibility to assess the effectiveness of the set dose of radiation energy, especially in the case of accelerated electron sterilisation. The spores of *Bacillus pumilus* (for example, ATCC 27.142, NCTC 10327, NCIMB 10692 or CIP 77.25) are recommended. The number of viable spores exceeds 1×10^7 per carrier. The *D*-value exceeds 1.9 kGy. It is verified that there is no growth of the reference micro-organisms after the biological indicators have been exposed to 25 kGy (*minimum absorbed dose*).

Gas sterilisation. The use of biological indicators is necessary for all gas sterilisation procedures, both for the validation of the cycles and for routine operations. Gas sterilisation is widely used for medical devices, isolators, chambers, etc. Use for such purposes is outside the scope of the European Pharmacopoeia. The use of spores of *Bacillus subtilis* (for example, var. *niger* ATCC 9372, NCIMB 8058 or CIP 77.18) is recommended for ethylene oxide. The number of viable spores exceeds 5×10^5 per carrier. The parameters of resistance are the following: the *D*-value exceeds 2.5 min for a test cycle involving 600 mg/l of ethylene oxide, at 54 °C and at 60 per cent relative humidity. It is verified that there is no growth of the reference micro-organisms after the biological indicators have been exposed to the test cycle described above for 60 min and that exposing the indicators to a reduced temperature cycle (600 mg/l, 30 °C and 60 per cent relative humidity) for 15 min leaves revivable spores. Exposing the indicators to 600 mg/l of ethylene oxide at 54 °C for 60 min without humidification must leave revivable spores to ensure that the biological indicator is able to reveal insufficient humidification.

01/2005:50103

5.1.3. EFFICACY OF ANTIMICROBIAL PRESERVATION

If a pharmaceutical preparation does not itself have adequate antimicrobial activity, antimicrobial preservatives may be added, particularly to aqueous preparations, to prevent proliferation or to limit microbial contamination which, during normal conditions of storage and use, particularly for multidose containers, could occur in a product and present

a hazard to the patient from infection and spoilage of the preparation. Antimicrobial preservatives must not be used as a substitute for good manufacturing practice.

The efficacy of an antimicrobial preservative may be enhanced or diminished by the active constituent of the preparation or by the formulation in which it is incorporated or by the container and closure used. The antimicrobial activity of the preparation in its final container is investigated over the period of validity to ensure that such activity has not been impaired by storage. Such investigations may be carried out on samples removed from the final container immediately prior to testing.

During development of a pharmaceutical preparation, it shall be demonstrated that the antimicrobial activity of the preparation as such or, if necessary, with the addition of a suitable preservative or preservatives provides adequate protection from adverse effects that may arise from microbial contamination or proliferation during storage and use of the preparation.

The efficacy of the antimicrobial activity may be demonstrated by the test described below. The test is not intended to be used for routine control purposes.

TEST FOR EFFICACY OF ANTIMICROBIAL PRESERVATION

The test consists of challenging the preparation, wherever possible in its final container, with a prescribed inoculum of suitable micro-organisms, storing the inoculated preparation at a prescribed temperature, withdrawing samples from the container at specified intervals of time and counting the organisms in the samples so removed.

The preservative properties of the preparation are adequate if, in the conditions of the test, there is a significant fall or no increase, as appropriate, in the number of micro-organisms in the inoculated preparation after the times and at the temperatures prescribed. The criteria of acceptance, in terms of decrease in the number of micro-organisms with time, vary for different types of preparations according to the degree of protection intended (see Tables 5.1.3.-1/2/3).

Test micro-organisms

<i>Pseudomonas aeruginosa</i>	ATCC 9027; NCIMB 8626; CIP 82.118.
<i>Staphylococcus aureus</i>	ATCC 6538; NCTC 10788; NCIMB 9518; CIP 4.83.
<i>Candida albicans</i>	ATCC 10231; NCPF 3179; IP 48.72.
<i>Aspergillus niger</i>	ATCC 16404; IMI 149007; IP 1431.83.

Single-strain challenges are used and the designated micro-organisms are supplemented, where appropriate, by other strains or species that may represent likely contaminants to the preparation. It is recommended, for example, that *Escherichia coli* (ATCC 8739; NCIMB 8545; CIP 53.126) is used for all oral preparations and *Zygosaccharomyces rouxii* (NCYC 381; IP 2021.92) for oral preparations containing a high concentration of sugar.

Preparation of inoculum

Preparatory to the test, inoculate the surface of agar medium B (2.6.12) for bacteria or agar medium C without the addition of antibiotics (2.6.12) for fungi, with the recently grown stock culture of each of the specified micro-organisms. Incubate the bacterial cultures at 30-35 °C for 18-24 h, the culture of *C. albicans* at 20-25 °C for 48 h, and the culture of *A. niger* at 20-25 °C for 1 week or until good sporulation is obtained. Subcultures may be needed after revival before the

micro-organism is in its optimal state, but it is recommended that their number be kept to a minimum.

To harvest the bacterial and *C. albicans* cultures, use a sterile suspending fluid, containing 9 g/l of *sodium chloride R*, for dispersal and transfer of the surface growth into a suitable vessel. Add sufficient suspending fluid to reduce the microbial count to about 10⁸ micro-organisms per millilitre. To harvest the *A. niger* culture, use a sterile suspending fluid containing 9 g/l of *sodium chloride R* and 0.5 g/l of *polysorbate 80 R* and adjust the spore count to about 10⁸ per millilitre by adding the same solution.

Remove immediately a suitable sample from each suspension and determine the number of colony-forming units per millilitre in each suspension by plate count or membrane filtration (2.6.12). This value serves to determine the inoculum and the baseline to use in the test. The suspensions shall be used immediately.

METHOD

To count the viable micro-organisms in the inoculated products, use the agar medium used for the initial cultivation of the respective micro-organisms.

Inoculate a series of containers of the product to be examined, each with a suspension of one of the test organisms to give an inoculum of 10⁵ to 10⁶ micro-organisms per millilitre or per gram of the preparation. The volume of the suspension of inoculum does not exceed 1 per cent of the volume of the product. Mix thoroughly to ensure homogeneous distribution.

Maintain the inoculated product at 20-25 °C, protected from light. Remove a suitable sample from each container, typically 1 ml or 1 g, at zero hour and at appropriate intervals according to the type of the product and determine the number of viable micro-organisms by plate count or membrane filtration (2.6.12). Ensure that any residual antimicrobial activity of the product is eliminated by dilution, by filtration or by the use of a specific inactivator. When dilution procedures are used, due allowance is made for the reduced sensitivity in the recovery of small numbers of viable micro-organisms. When a specific inactivator is used, the ability of the system to support the growth of the test organisms is confirmed by the use of appropriate controls.

The procedure is validated to verify its ability to demonstrate the required reduction in count of viable micro-organisms.

CRITERIA OF ACCEPTANCE

The criteria for evaluation of antimicrobial activity are given in Tables 5.1.3.-1/2/3 in terms of the log reduction in the number of viable micro-organisms against the value obtained for the inoculum.

Table 5.1.3.-1. - Parenteral and ophthalmic preparations

		Log reduction				
		6 h	24 h	7 d	14 d	28 d
Bacteria	A	2	3	-	-	NR*
	B	-	1	3	-	NI**
Fungi	A	-	-	2	-	NI
	B	-	-	-	1	NI

*NR: no recover

**NI: no increase

The A criteria express the recommended efficacy to be achieved. In justified cases where the A criteria cannot be attained, for example for reasons of an increased risk of adverse reactions, the B criteria must be satisfied.

Table 5.1.3.-2. - *Topical preparations*

		Log reduction			
		2 d	7 d	14 d	28 d
Bacteria	A	2	3	-	NI
	B	-	-	3	NI
Fungi	A	-	-	2	NI
	B	-	-	1	NI

The A criteria express the recommended efficacy to be achieved. In justified cases where the A criteria cannot be attained, for example for reasons of an increased risk of adverse reactions, the B criteria must be satisfied.

Table 5.1.3.-3. - *Oral preparations*

		Log reduction	
		14 d	28 d
Bacteria		3	NI
Fungi		1	NI

The above criteria express the recommended efficacy to be achieved.

01/2005:50104

5.1.4. MICROBIOLOGICAL QUALITY OF PHARMACEUTICAL PREPARATIONS

The following chapter is published for information.

In the manufacture, packaging, storage and distribution of pharmaceutical preparations, suitable means must be taken to ensure their microbiological quality. The pharmaceutical preparations should comply with the criteria given below.

Category 1

Preparations required to be sterile by the relevant monograph on the dosage form and other preparations labelled sterile.

- Test for sterility (2.6.1).

Category 2

Preparations for topical use and for use in the respiratory tract except where required to be sterile and transdermal patches.

- Total viable aerobic count (2.6.12). Not more than 10^2 micro-organisms (aerobic bacteria plus fungi) per gram, per millilitre or per patch (including the adhesive and backing layer).
- Transdermal patches: absence of enterobacteria and certain other gram-negative bacteria, determined on 1 patch (including the adhesive and backing layer). Other preparations: not more than 10^1 enterobacteria and certain other gram-negative bacteria per gram or per millilitre (2.6.13).
- Absence of *Pseudomonas aeruginosa*, determined on 1 g, 1 ml or one patch (including the adhesive and backing layer) (2.6.13).
- Absence of *Staphylococcus aureus*, determined on 1 g, 1 ml or one patch (including the adhesive and backing layer) (2.6.13).

Category 3

A. Preparations for oral and rectal administration.

- Total viable aerobic count (2.6.12). Not more than 10^3 bacteria and not more than 10^2 fungi per gram or per millilitre.
- Absence of *Escherichia coli* (1 g or 1 ml) (2.6.13).

B. Preparations for oral administration containing raw materials of natural (animal, vegetable or mineral) origin for which antimicrobial pretreatment is not feasible and for which the competent authority accepts microbial contamination of the raw material exceeding 10^3 viable micro-organisms per gram or per millilitre. Herbal medicinal products described in category 4 are excluded.

- Total viable aerobic count (2.6.12). Not more than 10^4 bacteria and not more than 10^2 fungi per gram or per millilitre.
- Not more than 10^2 enterobacteria and certain other gram-negative bacteria per gram or per millilitre (2.6.13).
- Absence of *Salmonella* (10 g or 10 ml) (2.6.13).
- Absence of *Escherichia coli* (1 g or 1 ml) (2.6.13).
- Absence of *Staphylococcus aureus* (1 g or 1 ml) (2.6.13).

Category 4

Herbal medicinal products consisting solely of one or more herbal drugs (whole, reduced or powdered).

A. Herbal medicinal products to which boiling water is added before use.

- Total viable aerobic count (2.6.12). Not more than 10^7 bacteria and not more than 10^5 fungi per gram or per millilitre.
- Not more than 10^2 *Escherichia coli* per gram or per millilitre (2.6.13, using suitable dilutions).

B. Herbal medicinal products to which boiling water is not added before use.

- Total viable aerobic count (2.6.12). Not more than 10^5 bacteria and not more than 10^4 fungi per gram or per millilitre.
- Not more than 10^3 enterobacteria and certain other gram-negative bacteria per gram or per millilitre (2.6.13).
- Absence of *Escherichia coli* (1 g or 1 ml) (2.6.13).
- Absence of *Salmonella* (10 g or 10 ml) (2.6.13).

01/2005:50105

5.1.5. APPLICATION OF THE F_0 CONCEPT TO STEAM STERILISATION OF AQUEOUS PREPARATIONS

The following chapter is published for information.

The F_0 value of a saturated steam sterilisation process is the lethality expressed in terms of the equivalent time in minutes at a temperature of 121 °C delivered by the process to the product in its final container with reference to micro-organisms possessing a Z-value of 10.

The total F_0 of a process takes account of the heating up and cooling down phases of the cycle and can be calculated by integration of lethal rates with respect to time at discrete temperature intervals.

When a steam sterilisation cycle is chosen on the basis of the F_0 concept, great care must be taken to ensure that an adequate assurance of sterility is consistently

achieved. In addition to validating the process, it may also be necessary to perform continuous, rigorous microbiological monitoring during routine production to demonstrate that the microbiological parameters are within the established tolerances so as to give an SAL of 10^{-6} or better.

In connection with sterilisation by steam, the Z -value relates the heat resistance of a micro-organism to changes in temperature. The Z -value is the change in temperature required to alter the D -value by a factor of 10.

The D -value (or decimal reduction value) is the value of a parameter of sterilisation (duration or absorbed dose) required to reduce the number of viable organisms to 10 per cent of the original number. It is only of significance under precisely defined experimental conditions.

The following mathematical relationships apply:

$$F_0 = D_{121} (\log N_0 - \log N) = D_{121} \log IF$$

D_{121} = D -value of the reference spores (5.1.2) at 121 °C,

N_0 = initial number of viable micro-organisms,

N = final number of viable micro-organisms,

IF = inactivation factor.

$$Z = \frac{T_2 - T_1}{\log D_1 - \log D_2}$$

D_1 = D -value of the micro-organism at temperature T_1 ,

D_2 = D -value of the micro-organism at temperature T_2 .

$$IF = N_0 - N = 10^{t/D}$$

t = exposure time,

D = D -value of micro-organism in the exposure conditions.

5.2. GENERAL TEXTS ON VACCINES

01/2005:50201

5.2.1. TERMINOLOGY USED IN MONOGRAPHS ON VACCINES

For some items, alternative terms commonly used in connection with veterinary vaccines are shown in parenthesis.

Seed-lot system. A seed-lot system is a system according to which successive batches of a product are derived from the same master seed lot. For routine production, a working seed lot may be prepared from the master seed lot. The origin and the passage history of the master seed lot and the working seed lot are recorded.

Master seed lot. A culture of a micro-organism distributed from a single bulk into containers and processed together in a single operation in such a manner as to ensure uniformity and stability and to prevent contamination. A master seed lot in liquid form is usually stored at or below -70°C . A freeze-dried master seed lot is stored at a temperature known to ensure stability.

Working seed lot. A culture of a micro-organism derived from the master seed lot and intended for use in production. Working seed lots are distributed into containers and stored as described above for master seed lots.

Cell-bank system (Cell-seed system). A system whereby successive final lots (batches) of a product are manufactured by culture in cells derived from the same master cell bank (master cell seed). A number of containers from the master cell bank (master cell seed) are used to prepare a working cell bank (working cell seed). The cell-bank system (cell-seed system) is validated for the highest passage level achieved during routine production.

Master cell bank (Master cell seed). A culture of cells distributed into containers in a single operation, processed together and stored in such a manner as to ensure uniformity and stability and to prevent contamination. A master cell bank (master cell seed) is usually stored at -70°C or lower.

Working cell bank (Working cell seed). A culture of cells derived from the master cell bank (master cell seed) and intended for use in the preparation of production cell cultures. The working cell bank (working cell seed) is distributed into containers, processed and stored as described for the master cell bank (master cell seed).

Primary cell cultures. Cultures of cells obtained by trypsinisation of a suitable tissue or organ. The cells are essentially identical to those of the tissue of origin and are no more than 5 *in vitro* passages from the initial preparation from the animal tissue.

Cell lines. Cultures of cells that have a high capacity for multiplication *in vitro*. In diploid cell lines, the cells have essentially the same characteristics as those of the tissue of origin. In continuous cell lines, the cells are able to multiply indefinitely in culture and may be obtained from healthy or tumoral tissue. Some continuous cell lines have oncogenic potential under certain conditions.

Production cell culture. A culture of cells intended for use in production; it may be derived from one or more containers of the working cell bank (working cell seed) or it may be a primary cell culture.

Control cells. A quantity of cells set aside, at the time of virus inoculation, as uninfected cell cultures. The uninfected cells are incubated under similar conditions to those used for the production cell cultures.

Single harvest. Material derived on one or more occasions from a single production cell culture inoculated with the same working seed lot or a suspension derived from the working seed lot, incubated, and harvested in a single production run.

Monovalent pooled harvest. Pooled material containing a single strain or type of micro-organism or antigen and derived from a number of eggs, cell culture containers etc. that are processed at the same time.

Final bulk vaccine. Material that has undergone all the steps of production except for the final filling. It consists of one or more monovalent pooled harvests, from cultures of one or more species or types of micro-organism, after clarification, dilution or addition of any adjuvant or other auxiliary substance. It is treated to ensure its homogeneity and is used for filling the containers of one or more final lots (batches).

Final lot (Batch). A collection of closed, final containers or other final dosage units that are expected to be homogeneous and equivalent with respect to risk of contamination during filling or preparation of the final product. The dosage units are filled, or otherwise prepared, from the same final bulk vaccine, freeze-dried together (if applicable) and closed in one continuous working session. They bear a distinctive number or code identifying the final lot (batch). Where a final bulk vaccine is filled and/or freeze-dried on several separate sessions, there results a related set of final lots (batches) that are usually identified by the use of a common part in the distinctive number or code; these related final lots (batches) are sometimes referred to as sub-batches, sub-lots or filling lots.

Combined vaccine. A multicomponent preparation formulated so that different antigens are administered simultaneously. The different antigenic components are intended to protect against different strains or types of the same organism and/or different organisms. A combined vaccine may be supplied by the manufacturer either as a single liquid or freeze-dried preparation or as several constituents with directions for admixture before use.

01/2005:50202

5.2.2. CHICKEN FLOCKS FREE FROM SPECIFIED PATHOGENS FOR THE PRODUCTION AND QUALITY CONTROL OF VACCINES

INTRODUCTION

Where specified in a monograph, chickens, embryos or cell cultures used for the production or quality control of vaccines are derived from eggs produced by chicken flocks free from specified pathogens (SPF). The SPF status of a flock is ensured by means of the system described below. The list of micro-organisms given is based on current knowledge and will be updated as necessary.

GENERAL PRINCIPLES AND PROCEDURES

A flock is defined as a group of birds sharing a common environment and having their own caretakers who have no contact with non-SPF flocks. Once a flock is defined, no non-SPF birds are added to it.

For SPF flocks established on a rolling basis, all replacements are hatched and reared in the controlled environment house. Subject to the agreement of the competent authorities, SPF embryos derived from a tested SPF flock from another house on the same site may be introduced. From 8 weeks of age, these replacement birds are regarded as a flock and monitored monthly in accordance with the Subsequent Testing requirements. At point of lay, all these replacement birds are tested in accordance with the Initial Testing requirements.

The flock is housed so as to minimise the chance of contamination. It is not sited near to non-SPF flocks of birds and is housed in an isolator or on wire in a building with filtered air under positive pressure. Appropriate measures are taken to prevent access of rodents, wild birds, insects and unauthorised people.

Personnel authorised to enter must have no contact with other birds or with agents likely to infect the flock. It is advisable for personnel to shower and change clothing or to wear protective clothing before entering the chicken house.

Items taken into the flock are sterilised. The feed is suitably treated to avoid the introduction of undesirable micro-organisms and water is obtained from a chlorinated supply. No medication is given that could interfere with detection of disease in the flock.

A permanent record is kept of the general health of the flock and any abnormality is investigated. Factors to be monitored include morbidity, mortality, general physical condition, feed consumption, daily egg production and egg quality, fertility and hatchability. Dirty eggs are discarded; clean eggs may be surface-disinfected whilst warm.

The flock originates from chickens shown to be free from vertically-transmitted agents. In particular, each chicken from which the flock is derived is tested repeatedly to ensure freedom from leucosis viruses and their antibodies. In order to establish the SPF status of a flock, it is kept under SPF conditions for a test period of not less than 4 months. Each bird in the entire flock is shown to be free from evidence of infection with the agents listed below under Initial Testing after 6 weeks and at the end of the test period.

For each new generation in an established flock, all of the birds in the flock are tested at not later than 20 weeks of age, using the tests prescribed below under Initial Testing. After the initial test, monthly tests are carried out on a representative 5 per cent sample (but not less than ten and not more than two hundred birds), using the tests prescribed below under Subsequent Testing, with a final test at 4 weeks after the last collection of eggs.

For all tests, blood samples are collected from an appropriate number of birds at the specified time. The resultant serum samples are examined for antibodies against the relevant agents. Serum-neutralisation tests are done on pools of not more than five sera. All other tests are done on each individual serum. Positive and negative controls are used in all tests. The reagents used in the tests are standardised against international or European standard reagents where these are available. For avian leucosis virus, in addition to tests for antibodies carried out on serum samples, appropriate samples are taken for testing for the virus.

In addition to serological tests, clinical examination is carried out at least once per week to verify that the birds are free from fowl-pox and signs of other infections. Necropsy and, where necessary to confirm diagnosis, histopathological examination are carried out on any bird that dies to verify that there is no sign of infection. The absence of *Salmonella*

spp. is determined by cultural examination of faecal samples at least once every 4 weeks; a pool of up to ten samples may be used for the tests.

If a positive result is obtained in any test carried out to establish the SPF status of a flock, the flock may not be designated as an SPF flock. If a positive result is obtained in any test carried out on an established flock, the flock loses its SPF status. Special provisions apply to chick anaemia agent (CAA) as described below. Any chickens, embryos or cell cultures collected since the previous negative test are not suitable for use: any product made from them must be discarded and any quality control tests done with them are invalid and must be repeated.

In order to regain SPF status, the flock is maintained under SPF conditions and routine 5 per cent monthly testing shall continue except that every bird in the entire flock is tested every month for infection with the particular agent that gave the positive result. Infected birds and their progeny are removed from the flock. SPF status is regained after two such consecutive tests have yielded completely negative results.

A positive result for CAA does not necessarily exclude use of material derived from the flock, but live vaccines for use in birds less than 7 days old must be produced using material from CAA-negative flocks. Inactivated vaccines for use in birds less than 7 days old may be produced using material from flocks that have not been shown to be free from CAA, provided it has been demonstrated that the inactivation process inactivates CAA.

Permanent records of mortality and of results of flock testing are kept for a minimum of five years. Details of any deterioration in egg production or hatchability, except for accidental cases identified as being of non-infectious origin, and of any test results indicating infection with a specified agent, are immediately submitted to the user of the eggs.

INITIAL TESTING

Subject to agreement by the competent authority, other types of test may be used provided they are at least as sensitive as those indicated and of appropriate specificity.

Micro-organism	Type of test
Avian adenoviruses	Enzyme-linked immuno-sorbent assay
Avian encephalomyelitis virus	Enzyme-linked immuno-sorbent assay
Avian infectious bronchitis virus	Enzyme-linked immuno-sorbent assay
Avian infectious laryngotracheitis virus	Serum neutralisation
Avian leucosis viruses	Enzyme-linked immuno-sorbent assay for virus and serum neutralisation for antibody
Avian nephritis virus	Fluorescent antibody
Avian reoviruses	Enzyme-linked immuno-sorbent assay
Avian reticuloendotheliosis virus	Fluorescent antibody
Chick anaemia agent	Fluorescent antibody
Haemagglutinating avian adenovirus (Egg drop syndrome 76- EDS 76 virus)	Haemagglutination inhibition
Infectious bursal disease virus	Serum neutralisation against each serotype present in the country of origin
Influenza A virus	Enzyme-linked immuno-sorbent assay
Marek's disease virus	Enzyme-linked immuno-sorbent assay

Micro-organism	Type of test
Newcastle disease virus	Haemagglutination inhibition
Turkey rhinotracheitis virus	Enzyme-linked immuno-sorbent assay
<i>Mycoplasma gallisepticum</i>	Agglutination and, to confirm a positive test, haemagglutination inhibition
<i>Mycoplasma synoviae</i>	Agglutination and, to confirm a positive test, haemagglutination inhibition
<i>Salmonella pullorum</i>	Agglutination

SUBSEQUENT TESTING

Subject to agreement by the competent authority, other types of test may be used provided they are at least as sensitive as those indicated and of appropriate specificity.

Micro-organism	Type of test
Avian adenoviruses	Enzyme-linked immuno-sorbent assay
Avian encephalomyelitis virus	Enzyme-linked immuno-sorbent assay
Avian infectious bronchitis virus	Enzyme-linked immuno-sorbent assay
Avian infectious laryngotracheitis virus	Serum neutralisation
Avian leucosis viruses	Enzyme-linked immuno-sorbent assay for the antibody
Avian nephritis virus	Fluorescent antibody
Avian reoviruses	Fluorescent antibody
Avian reticuloendotheliosis virus	Fluorescent antibody
Chick anaemia agent	Fluorescent antibody
Haemagglutinating avian adenovirus	Haemagglutination inhibition
Infectious bursal disease virus	Immunodiffusion against each serotype present in the country of origin
Influenza A virus	Enzyme-linked immuno-sorbent assay
Marek's disease virus	Enzyme-linked immuno-sorbent assay
Newcastle disease virus	Haemagglutination inhibition
Turkey rhinotracheitis virus	Enzyme-linked immuno-sorbent assay
<i>Mycoplasma gallisepticum</i>	Agglutination and, to confirm a positive test, haemagglutination inhibition
<i>Mycoplasma synoviae</i>	Agglutination and, to confirm a positive test, haemagglutination inhibition
<i>Salmonella pullorum</i>	Agglutination

01/2005:50203

5.2.3. CELL SUBSTRATES FOR THE PRODUCTION OF VACCINES FOR HUMAN USE

This general chapter deals with diploid cell lines and continuous cell lines used for the production of vaccines for human use; specific issues relating to vaccines prepared by recombinant DNA technology are covered by the monograph on *Products of recombinant DNA technology* (0784). Testing to be carried out at various stages (cell seed, master cell bank, working cell bank, cells at or beyond the maximum population doubling level used for production) is indicated in

Table 5.2.3-1. General provisions for the use of cell lines and test methods are given below. Where primary cells or cells that have undergone a few passages without constitution of a cell bank are used for vaccine production, requirements are given in the individual monograph for the vaccine concerned.

Diploid cell lines. A diploid cell line has a high but finite capacity for multiplication *in vitro*.

Continuous cell lines. A continuous cell line has the capacity to multiply indefinitely *in vitro*; the cells often have differences in karyotype compared to the original cells; they may be obtained from healthy or tumoral tissue.

For injectable vaccines produced in continuous cell lines, the purification process is validated to demonstrate removal of substrate-cell DNA to a level equivalent to not more than 10 ng per single human dose, unless otherwise prescribed.

Cell-bank system. Production of vaccines in diploid and continuous cell lines is based on a cell-bank system. The *in vitro* age of the cells is counted from the master cell bank. Each working cell bank is prepared from one or more containers of the master cell bank. The use, identity and inventory control of the containers is carefully documented.

Media and substances of animal and human origin. The composition of media used for isolation and all subsequent culture is recorded in detail and if substances of animal origin are used they must be free from extraneous agents. If human albumin is used, it complies with the monograph on *Human albumin solution* (0255).

Bovine serum used for the preparation and maintenance of cell cultures is tested and shown to be sterile and free from bovine viruses, notably bovine diarrhoea virus and mycoplasmas.

Trypsin used for the preparation of cell cultures is examined by suitable methods and shown to be sterile and free from mycoplasmas and viruses, notably pestiviruses and parvoviruses.

Cell seed. The data used to assess the suitability of the cell seed comprise information, where available, on source, history and characterisation.

Source of the cell seed. For human cell lines, the following information concerning the donor is recorded: ethnic and geographical origin, age, sex, general physiological condition, tissue or organ used, results of any tests for pathogens.

For animal cell lines, the following information is recorded concerning the source of the cells: species, strain, breeding conditions, geographical origin, age, sex, general physiological condition, tissue or organ used, results of any tests for pathogens.

Cells of neural origin, such as neuroblastoma and P12 cell lines, may contain substances that concentrate agents of spongiform encephalopathies and such cells are not used for vaccine production.

History of the cell seed. The following information is recorded: the method used to isolate the cell seed, culture methods and any other procedures used to establish the master cell bank, notably any that might expose the cells to extraneous agents.

Full information may not be available on the ingredients of media used in the past for cultivation of cells, for example on the source of substances of animal origin; where justified and authorised, cell banks already established using such media may be used for vaccine production.

Characterisation of the cell seed. The following properties are investigated:

(1) the identity of the cells (for example, isoenzymes, serology, nucleic acid fingerprinting);

Table 5.2.3.-1 – Testing of cell lines

Test	Cell seed	Master cell bank (MCB)	Working cell bank (WCB)	Cells at or beyond the maximum population doubling level used for production
1. IDENTITY AND PURITY				
Morphology	+	+	+	+
Relevant selection of the following tests: biochemical (e.g. isoenzymes), immunological (e.g. histocompatibility), cytogenetic markers, nucleic acid fingerprinting	+	+	+	+
Karyotype (diploid cell lines)	+	+	+(1)	+(1)
Life span (diploid cell lines)	–	+	+	–
2. EXTRANEIOUS AGENTS				
Bacterial and fungal contamination	–	+	+	–
Mycoplasmas	–	+	+	–
Tests in cell cultures	–	–	+	–
Co-cultivation	–	–	+(2)	+(2)
Tests in animals and eggs	–	–	+(2)	+(2)
Specific tests for possible contaminants depending on the origin of the cells (see above under Infectious extraneous agents)	–	–	+(2)	+(2)
Retroviruses	–	+(3)	–	+(3)
3. TUMORIGENICITY				
Tumorigenicity	–	–	–	+(4)

(1) The diploid character is established for each working cell bank but using cells at or beyond the maximum population doubling level used for production.

(2) Testing is carried out for each working cell bank, but using cells at or beyond the maximum population doubling level used for production.

(3) Testing is carried out for the master cell bank, but using cells at or beyond the maximum population doubling level used for production.

(4) The MRC-5 cell line, the WI-38 cell line and the FRhL-2 cell line are recognised as being non-tumorigenic and they need not be tested. Tests are not carried out on cell lines that are known or assumed to be tumorigenic.

(2) the growth characteristics of the cells and their morphological properties (light and electron microscopes);

(3) for diploid cell lines, karyotype;

(4) for diploid cell lines, the *in vitro* life span in terms of population doubling level.

Cell substrate stability. Suitable viability of the cell line in the intended storage conditions must be demonstrated. For a given product to be prepared in the cell line, it is necessary to demonstrate that consistent production can be obtained with cells at passage levels at the beginning and end of the intended span of use.

Infectious extraneous agents. Cell lines for vaccine production shall be free from infectious extraneous agents. Tests for extraneous agents are carried out as shown in Table 5.2.3.-1.

Depending on the origin and culture history of the cell line, it may be necessary to carry out tests for selected, specific potential contaminants, particularly those that are known to infect latently the species of origin, for example simian virus 40 in rhesus monkeys. For cell lines of rodent origin, antibody-production tests are carried out in mice, rats and hamsters to detect species-specific viruses.

Cell lines are examined for the presence of retroviruses as described below. Cell lines that show the presence of retroviruses capable of replication are not acceptable for production of vaccines.

Tumorigenicity. For the preparation of live vaccines, the cell line must not be tumorigenic at any population doubling level used for vaccine production. Where a tumorigenic cell

line is used for the production of other types of vaccine, the purification process is validated to demonstrate that residual substrate-cell DNA is reduced to less than 10 ng per single human dose of the vaccine, unless otherwise prescribed, and that substrate-cell protein is reduced to an acceptable level.

A cell line which is known to have tumorigenic potential does not have to be tested further. If a cell line is of unknown tumorigenic potential, it is either regarded as being tumorigenic or it is tested for tumorigenicity using an *in vitro* test as described below; if the result of the *in vitro* test is negative or not clearly positive, an *in vivo* test as described below is carried out. The tests are carried out using cells at or beyond the maximum population doubling level that will be used for vaccine production.

The MRC-5, the WI-38 and the FRhL-2 cell lines are recognised as being non-tumorigenic and further testing is not necessary.

Chromosomal characterisation. Diploid cell lines shall be shown to be diploid. More extensive characterisation of a diploid cell line by karyotype analysis is required if the removal of intact cells during processing after harvest has not been validated. Samples from four passage levels evenly spaced over the life-span of the cell line are examined. A minimum of 200 cells in metaphase are examined for exact count of chromosomes and for frequency of hyperploidy, hypoploidy, polyploidy, breaks and structural abnormalities.

The MRC-5, the WI-38 and the FRhL-2 cell lines are recognised as being diploid and well characterised; where they are not genetically modified, further characterisation is not necessary.

TEST METHODS FOR CELL CULTURES

Identification. Nucleic-acid-fingerprint analysis and a relevant selection of the following are used to establish the identity of the cells:

- (1) biochemical characteristics (isoenzyme analysis),
- (2) immunological characteristics (histocompatibility antigens),
- (3) cytogenetic markers.

Contaminating cells. The nucleic-acid-fingerprint analysis carried out for identification also serves to demonstrate freedom from contaminating cells.

Bacterial and fungal contamination. The master cell bank and each working cell bank comply with the test for sterility (2.6.1), carried out using for each medium 10 ml of supernatant fluid from cell cultures. Carry out the test on 1 per cent of the containers with a minimum of two containers.

Mycoplasmas (2.6.7). The master cell bank and each working cell bank comply with the test for mycoplasmas by the culture method and the indicator cell culture method. Use one or more containers for the test.

Test for extraneous agents in cell cultures. The cells comply with the test for haemadsorbing viruses and with the tests in cell cultures for other extraneous agents given in chapter 2.6.16 under Production cell culture: control cells. If the cells are of simian origin, they are also inoculated into rabbit kidney cell cultures to test for herpesvirus B (cercopithecid herpesvirus 1).

Co-cultivation. Co-cultivate intact and disrupted cells separately with other cell systems including human cells and simian cells. Carry out examinations to detect possible morphological changes. Carry out tests on the cell culture fluids to detect haemagglutinating viruses. The cells comply with the test if no evidence of any extraneous agent is found.

Retroviruses. Examine for the presence of retroviruses using:

- (1) infectivity assays,
- (2) transmission electron microscopy,
- (3) if tests (1) and (2) give negative results, reverse transcriptase assays (in the presence of magnesium and manganese) carried out on pellets obtained by high-speed centrifugation.

Tests in animals. Inject intramuscularly (or, for suckling mice, subcutaneously) into each of the following groups of animals 10^7 viable cells divided equally between the animals in each group:

- (1) two litters of suckling mice less than 24 h old, comprising not fewer than ten animals,
- (2) ten adult mice.

Inject intracerebrally into each of ten adult mice 10^6 viable cells to detect the possible presence of lymphocytic choriomeningitis virus.

Observe the animals for at least 4 weeks. Investigate animals that become sick or show any abnormality to establish the cause of illness. The cells comply with the test if no evidence of any extraneous agent is found. The test is invalid if fewer than 80 per cent of the animals in each group remain healthy and survive to the end of the observation period.

For cells obtained from a rodent species (for example, Chinese hamster ovary cells or baby hamster kidney cells), tests for antibodies against likely viral contaminants of the species in question are carried out on animals that have received injections of the cells.

Tests in eggs. Using an inoculum of 10^6 viable cells per egg, inoculate the cells into the allantoic cavity of ten SPF embryonated hens' eggs (5.2.2) 9 to 11 days old and into the yolk sac of ten SPF embryonated hens' eggs 5 to 6 days old. Incubate for not less than 5 days. Test the allantoic fluids for the presence of haemagglutinins using mammalian and avian red blood cells; carry out the test at 5 ± 3 °C and 20-25 °C and read the results after 30 min and 60 min. The cells comply with the test if no evidence of any extraneous agent is found. The test is invalid if fewer than 80 per cent of the embryos remain healthy and survive to the end of the observation period.

Tests for tumorigenicity *in vitro*. The following test systems may be used:

- (1) colony formation in soft agar gels,
- (2) production of invasive cell growth following inoculation into organ cultures,
- (3) study of transformation activity using, for example, the 3T3 assay system for active oncogenes.

Tests for tumorigenicity *in vivo*. The test consists in establishing a comparison between the cell line and a suitable positive control (for example, HeLa or Hep2 cells).

Animal systems that have been shown to be suitable for this test include:

- (1) athymic mice (Nu/Nu genotype),
- (2) newborn mice, rats or hamsters that have been treated with antithymocyte serum or globulin,
- (3) thymectomised and irradiated mice that have been reconstituted (T⁺, B⁺) with bone marrow from healthy mice.

Whichever animal system is selected, the cell line and the reference cells are injected into separate groups of 10 animals each. In both cases, the inoculum for each animal is 10^7 cells suspended in a volume of 0.2 ml, and the injection may be by either the intramuscular or subcutaneous route. Newborn animals are treated with 0.1 ml of antithymocyte serum or globulin on days 0, 2, 7 and 14 after birth. A potent serum or globulin is one that suppresses the immune mechanisms of growing animals to the extent that the subsequent inoculum of 10^7 positive reference cells regularly produces tumours and metastases. Severely affected animals showing evident progressively growing tumours are killed before the end of the test to avoid unnecessary suffering.

At the end of the observation period all animals, including the reference group(s), are killed and examined for gross and microscopic evidence of the proliferation of inoculated cells at the site of injection and in other organs (for example lymph nodes, lungs, kidneys and liver).

In all test systems, the animals are observed and palpated at regular intervals for the formation of nodules at the sites of injection. Any nodules formed are measured in two perpendicular dimensions, the measurements being recorded regularly to determine whether there is progressive growth of the nodule. Animals showing nodules which begin to regress during the period of observation are killed before the nodules are no longer palpable, and processed for histological examination. Animals with progressively growing nodules are observed for 1-2 weeks. Among those without nodule formation, half are observed for 3 weeks and half for 12 weeks before they are killed and processed for histological examination. A necropsy is performed on each animal and includes examination for gross evidence of tumour formation at the site of injection and in other organs such as lymph nodes, lungs, brain, spleen, kidneys and liver. All tumour-like lesions and the site of injection are examined histologically. In addition, since some cell lines may give rise

to metastases without evidence of local tumour growth, any detectable regional lymph nodes and the lungs of all animals are examined histologically.

The test is invalid if fewer than nine of ten animals injected with the positive reference cells show progressively growing tumours.

01/2005:50204

5.2.4. CELL CULTURES FOR THE PRODUCTION OF VETERINARY VACCINES

Cell cultures for the production of vaccines for veterinary use comply with the requirements of this section. It may also be necessary that cell cultures used for testing of vaccines for veterinary use also comply with some or all of these requirements.

For most mammalian viruses, propagation in cell lines is possible and the use of primary cells is then not acceptable.

Permanently infected cells used for production of veterinary vaccines comply with the appropriate requirements described below. The cells shall be shown to be infected only with the agent stated.

CELL LINES

Cell lines are normally handled according to a cell-seed system. Each master cell seed is assigned a specific code for identification purposes. The master cell seed is stored in aliquots at -70°C or lower. Production of vaccine is not normally undertaken on cells more than twenty passages from the master cell seed. Where suspension cultures are used, an increase in cell numbers equivalent to approximately three population doublings is considered equivalent to one passage. If cells beyond twenty passage levels are to be used for production, it shall be demonstrated, by validation or further testing, that the production cell cultures are essentially similar to the master cell seed with regard to their biological characteristics and purity and that the use of such cells has no deleterious effect on vaccine production.

The history of the cell line shall be known and recorded in detail (for example, origin, number of passages and media used for multiplication, storage conditions).

The method of storing and using the cells, including details of how it is ensured that the maximum number of passages permitted is not exceeded during product manufacture, are recorded. A sufficient quantity of the master cell seed and each working cell seed are kept for analytical purposes.

The tests described below are carried out (as prescribed in Table 5.2.4.-1) on a culture of the master cell seed and the working cell seed or on cell cultures from the working cell seed at the highest passage level used for production and derived from a homogeneous sample demonstrated to be representative.

Characteristics of culture. The appearance of cell monolayers, before and after histological staining, is described. Information, if possible numerical data, is provided especially on the speed and rate of growth. Similarly, the presence or absence of contact inhibition, polynucleated cells and any other cellular abnormalities are specified.

Karyotype. A chromosomal examination is made of not fewer than fifty cells undergoing mitosis in the master cell seed and at a passage level at least as high as that to be used in production. Any chromosomal marker present in the master cell seed must also be found in the high passage

cells and the modal number of chromosomes in these cells must not be more than 15 per cent higher than of cells of the master cell seed. The karyotypes must be identical. If the modal number exceeds the level stated, if the chromosomal markers are not found in the working cell seed at the highest level used for production or if the karyotype differs, the cell line shall not be used for manufacture.

Table 5.2.4.-1. – *Cell culture stage at which tests are carried out*

	Master cell seed	Working cell seed	Cell from working cell seed at highest passage level
General microscopy	+	+	+
Bacteria and fungi	+	+	–
Mycoplasmas	+	+	–
Viruses	+	+	–
Identification of species	+	–	+
Karyotype	+	–	+
Tumorigenicity	+	–	–

Identification of the species. It shall be shown, by one validated method, that the master cell seed and the cells from the working cell seed at the highest passage level used for production come from the species of origin specified. When a fluorescence test is carried out and the corresponding serum to the species of origin of cells is used and shows that all the tested cells are fluorescent, it is not necessary to carry out other tests with reagents able to detect contamination by cells of other species.

Bacterial and fungal contamination. The cells comply with the test for sterility (2.6.1). The sample of cells to be examined consists of not less than the number of cells in a monolayer with an area of 70 cm^2 or, for cells grown in suspension, an approximately equivalent number of cells. The cells are maintained in culture for at least 15 days without antibiotics before carrying out the test.

Mycoplasmas (2.6.7). The cells comply with the test for mycoplasmas. The cells are maintained in culture for at least 15 days without antibiotics before carrying out the test.

Absence of contaminating viruses. The cells must not be contaminated by viruses; suitably sensitive tests, including those prescribed below, are carried out.

The monolayers tested shall have an area of at least 70 cm^2 , and shall be prepared and maintained using medium and additives, and grown under similar conditions to those used for the preparation of the vaccine. The monolayers are maintained in culture for a total of at least 28 days. Subcultures are made at 7-day intervals, unless the cells do not survive for this length of time, when the subcultures are made on the latest day possible. Sufficient cells, in suitable containers, are produced for the final subculture to carry out the tests specified below.

The monolayers are examined regularly throughout the incubation period for the possible presence of cytopathic effects and at the end of the observation period for cytopathic effects, haemadsorbent viruses and specific viruses by immuno-fluorescence and other suitable tests as indicated below.

Detection of cytopathic viruses. Two monolayers of at least 6 cm^2 each are stained with an appropriate cytological stain. The entire area of each stained monolayer is examined for any inclusion bodies, abnormal numbers of giant cells or any other lesion indicative of a cellular abnormality which might be attributable to a contaminant.

Detection of haemadsorbent viruses. Monolayers totalling at least 70 cm² are washed several times with an appropriate buffer and a sufficient volume of a suspension of suitable red blood cells added to cover the surface of the monolayer evenly. After different incubation times cells are examined for the presence of haemadsorption.

Detection of specified viruses. Tests are carried out for freedom from contaminants specific for the species of origin of the cell line and for the species for which the product is intended. Sufficient cells on suitable supports are prepared to carry out tests for the agents specified. Suitable positive controls are included in each test. The cells are subjected to suitable tests, for example using fluorescein-conjugated antibodies or similar reagents.

Tests in other cell cultures. Monolayers totalling at least 140 cm² are required. The cells are frozen and thawed at least three times and then centrifuged to remove cellular debris. Inoculate aliquots onto the following cells at any time up to 70 per cent confluency:

- primary cells of the source species;
- cells sensitive to viruses pathogenic for the species for which the vaccine is intended;
- cells sensitive to pestiviruses.

The inoculated cells are maintained in culture for at least 7 days, after which freeze-thawed extracts are prepared as above and inoculated onto sufficient fresh cultures of the same cell types to allow for the testing as described below. The cells are incubated for at least a further 7 days. The cultures are examined regularly for the presence of any cytopathic changes indicative of living organisms.

At the end of this period of 14 days, the inoculated cells are subjected to the following checks:

- freedom from cytopathic and haemadsorbent organisms, using the methods specified in the relevant paragraphs above,
- absence of pestiviruses and other specific contaminants by immunofluorescence or other validated methods as indicated in the paragraph above on Detection of Specified Viruses.

Tumorigenicity. The risk of a cell line for the target species must be evaluated and, if necessary, tests are carried out.

PRIMARY CELLS

For most mammalian vaccines, the use of primary cells is not acceptable for the manufacture of vaccines since cell lines can be used. If there is no alternative to the use of primary cells, the cells are obtained from a herd or flock free from specified pathogens, with complete protection from introduction of diseases (for example, disease barriers, filters on air inlets, suitable quarantine before introduction of animals). Chicken flocks comply with the requirements prescribed under *Chicken Flocks Free from Specified Pathogens for the Production and Quality Control of Vaccines* (5.2.2). For all other species, the herd or flock is shown to be free from relevant specified pathogens. All the breeding stock in the herd or flock intended to be used to produce primary cells for vaccine manufacture is subject to a suitable monitoring procedure including regular serological checks carried out at least twice a year and two supplementary serological examinations performed in 15 per cent of the breeding stock in the herd between the two checks mentioned above.

Wherever possible, particularly for mammalian cells, a seed-lot system is used with, for example, a master cell seed formed after less than five passages, the working cell seed being no more than five passages from the initial preparation of the cell suspension from the animal tissues.

Each master cell seed, working cell seed and cells of the highest passage of primary cells are checked in accordance with Table 5.2.4.-2 and the procedure described below. The sample tested shall cover all the sources of cells used for the manufacture of the batch. No batches of vaccine manufactured using the cells may be released if any one of the checks performed produces unsatisfactory results.

Table 5.2.4.-2. – *Cell culture stage at which tests are carried out*

	Master cell seed	Working cell seed	Highest passage level
General microscopy	+	+	+
Bacteria and fungi	+	+	–
Mycoplasmas	+	+	–
Viruses	+	+	–
Identification of species	+	–	–

Characteristics of cultures. The appearance of cell monolayers, before and after histological staining, is described. Information, if possible numerical data, is recorded, especially on the speed and rate of growth. Similarly, the presence or absence of contact inhibition, polynucleated cells and any other cellular abnormalities are specified.

Identification of species. It shall be demonstrated by one validated test that the master cell seed comes from the specified species of origin.

When a fluorescence test is carried out and the corresponding serum to the species of origin of cells is used and shows that all the tested cells are fluorescent, it is not necessary to carry out other tests with reagents able to detect contamination by cells of other species.

Bacterial and fungal sterility. The cells comply with the test for sterility (2.6.1). The sample of cells to be examined consists of not less than the number of cells in a monolayer with an area of 70 cm² or for cells grown in suspension an approximately equivalent number of cells. The cells are maintained in culture for at least 15 days without antibiotics before carrying out the test.

Mycoplasmas (2.6.7). The cells comply with the test for mycoplasmas. The cells are maintained in culture for at least 15 days without antibiotics before carrying out the test.

Absence of contaminating viruses. The cells must not be contaminated by viruses; suitably sensitive tests, including those prescribed below are carried out.

The monolayers tested shall be at least 70 cm², and shall be prepared and maintained in culture using the same medium and additives, and under similar conditions to those used for the preparation of the vaccine.

The monolayers are maintained in culture for a total of at least 28 days or for the longest period possible if culture for 28 days is impossible. Subcultures are made at 7-day intervals, unless the cells do not survive for this length of time when the subcultures are made on the latest day possible. Sufficient cells, in suitable containers are produced for the final subculture to carry out the tests specified below.

The monolayers are examined regularly throughout the incubation period for the possible presence of cytopathic effects and at the end of the observation period for cytopathic effects, haemadsorbent viruses and specific viruses by immunofluorescence and other suitable tests as indicated below.

Detection of cytopathic viruses. Two monolayers of at least 6 cm² each are stained with an appropriate cytological stain. Examine the entire area of each stained monolayer for any inclusion bodies, abnormal numbers of giant cells or any other lesion indicative of a cellular abnormality that might be attributable to a contaminant.

Detection of haemadsorbent viruses. Monolayers totalling at least 70 cm² are washed several times with a suitable buffer solution and a sufficient volume of a suspension of suitable red blood cells added to cover the surface of the monolayer evenly. After different incubation times, examine cells for the presence of haemadsorption.

Detection of specified viruses. Tests are carried out for freedom of contaminants specific for the species of origin of the cells and for the species for which the product is intended.

Sufficient cells on suitable supports are prepared to carry out tests for the agents specified. Suitable positive controls are included in each test. The cells are subjected to suitable tests using fluorescein-conjugated antibodies or similar reagents.

Tests in other cell cultures. Monolayers totalling at least 140 cm² are required. The cells are frozen and thawed at least three times and then centrifuged to remove cellular debris. Aliquots are inoculated onto the following cells at any time up to 70 per cent confluency:

- primary cells of the source species;
- cells sensitive to viruses pathogenic for the species for which the vaccine is intended;
- cells sensitive to pestiviruses.

The inoculated cells are maintained in culture for at least 7 days, after which freeze-thawed extracts are prepared as above, and inoculated onto sufficient fresh cultures of the same cell types to allow for the testing as described below. The cells are incubated for at least a further 7 days. All cultures are regularly examined for the presence of any cytopathic changes indicative of living organisms.

At the end of this period of 14 days, the inoculated cells are subjected to the following checks:

- freedom from cytopathic and haemadsorbent organisms is demonstrated using the methods specified in the relevant paragraphs above;
- relevant substrates are tested for the absence of pestiviruses and other specific contaminants by immunofluorescence or other validated methods as indicated in the paragraph above on Detection of Specified Viruses.

01/2005:50205

5.2.5. SUBSTANCES OF ANIMAL ORIGIN FOR THE PRODUCTION OF VETERINARY VACCINES

Substances of animal origin (for example, serum, trypsin and serum albumin) may be used during the manufacture of veterinary immunological products, as ingredients of culture media etc. or as added constituents of vaccines or diluents. It is recommended to reduce, wherever practicable, the use of such substances.

Certain restrictions are placed upon the use of such substances to minimise the risk associated with pathogens that may be present in them.

- The use of substances of animal origin as constituents of vaccines or diluents is not generally acceptable except where such substances are sterilised by a suitable,

validated method. Where the use of such substances has been shown to be essential and sterilisation is not possible, the criteria described under Requirements apply.

- Substances of animal origin used during production are either subjected to a suitable, validated sterilisation or inactivation procedure or the substance is tested for the absence of extraneous organisms in accordance with the Requirements below. For inactivated vaccines, the method used for inactivation of the vaccine strain may also be validated for inactivation of possible contaminants from substances of animal origin.

In addition to the restrictions described below, manufacturers must consider restrictions on the handling of substances of animal origin in the vaccine manufacturing premises.

The restrictions imposed by these sections may need to be varied in accordance with changes in the incidence of disease in the country of origin and in Europe.

REQUIREMENTS

Substances of animal origin comply with the requirements of the Pharmacopoeia (where a relevant monograph exists).

Source. The risk related to the animal diseases occurring in the country of origin of the substance and to the potential infectious diseases occurring in the source species, in relation to the proposed recipient species must be carefully evaluated. The strictest possible selection criteria must be applied, in particular for substances for use in products intended for the same species and for substances of bovine, caprine, ovine and porcine origin.

Preparation. Substances of animal origin are prepared from a homogeneous bulk designated with a batch number. A batch may contain substances derived from as many animals as desired but once defined and given a batch number, the batch is not added to or contaminated in any way.

All batches of substances shall be shown to be free from contaminants as described below and/or are subject to a validated inactivation procedure.

Inactivation. The inactivation procedure chosen shall have been shown to be capable of reducing the titre of certain potential contaminants in the substance concerned by at least 10⁶. If this reduction in titre cannot be shown experimentally, kinetic studies for the inactivation procedure must be carried out and shown to be satisfactory, taking into account the possible level of contamination.

The list of potential contaminating organisms that the procedure must be shown to be capable of inactivating must be appropriate to the particular species of origin of the substance. The evidence for the efficacy of the procedure, which must relate to the current circumstances, may take the form of references to published literature or experimental data generated by the manufacturer.

Tests. For examination of the substance for freedom from contaminants, any solids are dissolved or suspended in a suitable medium in such a way as to create a solution or suspension containing at least 300 g/l of the substance to be examined. If the substance is not soluble or where cytotoxic reactions occur, a lower concentration may be used.

Any batch of substance found to contain living organisms of any kind is unsatisfactory and is either discarded or re-processed and shown to be satisfactory.

Freedom from extraneous viruses. The solution or suspension of the solid substance or the undiluted liquid substance is tested for contaminants by suitably sensitive methods. These methods shall include tests in suitably

sensitive cell cultures, including primary cells from the same species as the substances to be examined. A proportion of the cells is passaged at least twice.

The cells are observed regularly for 21 days for cytopathic effects. At the end of each 7 day period, a proportion of the original cultures is fixed, stained and examined for cytopathic effects; a proportion is tested for haemadsorbing agents; and a proportion is tested for specific agents by appropriate serodiagnostic tests.

Bacterial and fungal contamination. Before use, substances are tested for sterility (2.6.1) and freedom from mycoplasmas (2.6.7) or sterilised to inactivate any bacterial, fungal or mycoplasmal contaminants.

01/2005:50206

5.2.6. EVALUATION OF SAFETY OF VETERINARY VACCINES

During the development of the vaccine, safety tests are carried out in the target species to show the risks from use of the vaccine. Live vaccines are prepared only from strains of organisms that have been shown to be safe.

In the tests, "dose" means that quantity of the product to be recommended for use and containing the maximum titre or potency likely to be contained in production batches. For live vaccines, a batch or batches of vaccine prepared from the least attenuated passage to be used for production shall be used in the tests.

The safety of each of the components of combined vaccines and the safety of the combined product shall be demonstrated. For inactivated vaccines, safety tests carried out on the combined vaccine may be regarded as sufficient to demonstrate the safety of the individual components.

The tests described below, modified or supplemented by tests described in the Production section of a specific monograph may be carried out as part of the tests necessary during development to demonstrate the safety of a vaccine.

A. LABORATORY TESTS

Safety of the administration of one dose. For each of the recommended routes of administration, administer one dose of vaccine to susceptible animals of each species and category for which use of the vaccine is to be recommended. This must include animals of the youngest recommended age and pregnant animals, if appropriate. The animals are observed and examined for signs of abnormal local and systemic reactions. Where appropriate, these studies shall include detailed post-mortem macroscopic and microscopic examinations of the injection site; such examinations are not usually necessary for non-food animals. Other objective criteria are recorded, such as rectal temperature (for mammals) and performance measurements. The rectal temperatures are recorded on at least the day before vaccination, at the time of vaccination, 4 h after vaccination and on the following 4 days. The animals are observed and examined until reactions may no longer be expected but, in all cases, the observation and examination period extends at least until 14 days after administration.

As part of these studies, examination of reproductive performance must also be considered when data suggest that the starting material from which the product is derived may be a risk factor. Where prescribed in a monograph, reproductive performance of males and non-pregnant and pregnant females and harmful effects on the progeny, including teratogenic and abortifacient effects, are investigated.

Safety of one administration of an overdose. An overdose of the product is administered by each recommended route of administration to animals of the most sensitive categories of the target species, including animals of the youngest age and pregnant animals, if appropriate. The overdose normally consists of 10 doses of a live vaccine or 2 doses of an inactivated product. The animals are observed and examined for signs of local and systemic reactions. Other objective criteria are recorded, such as rectal temperature (for mammals) and performance measurements. The animals are observed and examined for at least 14 days after administration.

Safety of the repeated administration of one dose. Repeated administration of one dose may be required to reveal any adverse effects induced by such administration. These tests are carried out on the most sensitive categories of the target species, using the recommended route of administration. The animals are observed and examined for at least 14 days after the last administration for signs of systemic and local reactions. Other objective criteria are recorded, such as rectal temperature (for mammals) and performance measurements.

Residues. It is not normally necessary to undertake a study of residues. However, where adjuvants and/or preservatives are used in the manufacture of veterinary vaccines, consideration shall be given to the possibility of any residue remaining in the foodstuffs. If necessary, the effects of such residues are investigated. Moreover, in the case of live vaccines for well established zoonotic diseases, the determination of residual vaccine organisms at the injection site may be required, in addition to the studies of dissemination described below.

Adverse effects on immunological functions. Where the vaccine might adversely affect the immune response of the vaccinated animal or of its progeny, suitable tests on the immunological functions are carried out.

Special requirements for live vaccines. The following laboratory tests must also be carried out with live vaccines.

a) Spread of the vaccine strain. Spread of the vaccine strain from vaccinated to unvaccinated target animals is investigated using the recommended route of administration most likely to result in spread. Moreover, it may be necessary to investigate the safety of spread to non-target species that could be highly susceptible to a live vaccine strain. An assessment must be made of how many animal-to-animal passages are likely to be sustainable under normal circumstances together with an assessment of the likely consequences.

b) Dissemination in vaccinated animal. Faeces, urine, milk, eggs, oral, nasal and other secretions shall be tested for the presence of the organism. Moreover, studies may be required of the dissemination of the vaccine strain in the body, with particular attention being paid to the predilection sites for replication of the organism. In the case of live vaccines for well-established zoonotic diseases for food-producing animals, these studies are obligatory.

c) Reversion to or increase in virulence. For attenuated vaccines, use material from the passage level that is least attenuated for the target species between the master seed lot and the final product. For other live vaccines, use material from the passage likely to have maximum virulence for the target species. The initial vaccination is carried out using the recommended route of administration most likely to lead to reversion to virulence. After this, not fewer than 5 further serial passages through animals of the target species are undertaken. Where this is not technically possible due to failure of the organism to replicate adequately, the test is repeated and as many passages as possible are carried out in

the target species. If necessary, *in vitro* propagation of the organism may be carried out between two passages *in vivo*. The passages are undertaken by the route of administration most likely to lead to reversion to virulence. Not fewer than two fully susceptible animals are used for each passage. At each passage, the presence of living vaccine-derived organisms in the material used for passage is demonstrated. The safety of material from the highest successful passage is compared with that of unpassaged material.

For particular viruses, a monograph may require more passages in more animals if there is an indication from available data that this is relevant. At least the final passage is done using animals most appropriate to the potential risk being assessed.

d) Biological properties of the vaccine strain. Other tests may be necessary to determine as precisely as possible the intrinsic biological properties of the vaccine strain (for example, neurotropism). For vector vaccines, evaluation is made of the risk of changing the tropism or virulence of the strain and where necessary specific tests are carried out. Such tests are systematically carried out where the product of a foreign gene is incorporated into the strain as a structural protein.

e) Recombination or genomic reassortment of strain. The probability of recombination or genomic reassortment with field or other strains shall be considered.

B. FIELD STUDIES

Results from laboratory studies shall normally be supplemented with supportive data from field studies.

For food-producing mammals, the studies include measurement of the rectal temperatures of a sufficient number of animals, before and after vaccination; for other mammals, such measurements are carried out if the laboratory studies indicate that there might be a problem. The size and persistence of any local reaction and the proportion of animals showing local or systemic reactions are recorded. Performance measurements are made, where appropriate.

C. ECOTOXICITY

An assessment is made of the potential harmful effects of the vaccine for the environment and any necessary precautionary measures to reduce such risks are identified. The likely degree of exposure of the environment to the vaccine is assessed taking into account: the target species and mode of administration; excretion of the product; disposal of unused vaccine. If these factors indicate that there will be significant exposure of the environment to the product, the potential ecotoxicity is evaluated taking into account the properties of the vaccine as determined, for example, in the tests described in this section.

methods of vaccination and using the recommended schedule to animals of each species and category for which use of the vaccine is to be recommended. The type of efficacy testing to be carried out varies considerably depending on the particular type of vaccine.

As part of or in addition to tests carried out during development to establish efficacy, the tests described in the Production section of a specific monograph may be carried out; the following must be taken into account.

The dose to be used is that quantity of the product to be recommended for use and containing the minimum titre or potency expected at the end of the period of validity.

For live vaccines, vaccine prepared from the most attenuated passage to be used for production is used.

The efficacy evidence must support all the claims being made. For example, claims for protection against respiratory disease must be supported by at least evidence of protection from clinical signs of respiratory disease. Where it is claimed that there is protection from infection this must be demonstrated using re-isolation techniques. If more than one claim is made, supporting evidence for each claim is required.

The influence of passively acquired and maternally derived antibodies on the efficacy of a vaccine is adequately evaluated. Any claims, stated or implied, regarding onset and duration of protection shall be supported by data from trials.

The efficacy of each of the components of multivalent and combined products shall be demonstrated using the combined vaccine.

Studies of immunological compatibility are undertaken when simultaneous administration is recommended or where it is a part of a usual vaccination schedule. Wherever a product is to be recommended as part of a vaccination scheme, the priming or booster effect or the contribution of the product to the efficacy of the scheme as a whole shall be demonstrated.

LABORATORY TESTS

In principle, demonstration of efficacy is undertaken under well-controlled laboratory conditions by challenge after administration of the product to the target animal under the recommended conditions of use. Challenge is carried out using a strain different from the one used in the production of the vaccine. In so far as possible, the conditions under which the challenge is carried out shall mimic the natural conditions for infection, for example with regard to the amount of challenge organism and the route of administration of the challenge.

If possible, the immune mechanism (cell-mediated/humoral, local/general, classes of immunoglobulin) that is initiated after the administration of the vaccine to target animals shall be determined.

FIELD TRIALS

In general, results from laboratory tests are supplemented with data from field trials, carried out with untreated control animals. Where laboratory trials cannot be supportive of efficacy, the performance of field trials alone may be acceptable.

1. INTRODUCTION

1-1. SCIENTIFIC BACKGROUND

Transmissible Spongiform Encephalopathies (TSEs) are chronic degenerative nervous diseases characterised by the accumulation of an abnormal isoform of a cellular glycoprotein known as PrP (or prion protein). The abnormal isoform of PrP (PrP^{Sc}) differs from normal PrP (PrP^C) in being highly resistant to protease and heat denaturation treatments. PrP^{Sc} is considered to be the infective agent responsible for transmitting TSE disease.

TSE diseases in animals include:

- bovine spongiform encephalopathy (BSE) in cattle,
- scrapie in sheep and goats,
- chronic wasting disease (CWD) in cervids (deer and elk),

- transmissible mink encephalopathy (TME) in farmed mink,
- feline spongiform encephalopathy (FSE) in felidae (specifically domestic cats and captive large cats), and
- spongiform encephalopathy of exotic ungulates in zoos.

In humans, spongiform encephalopathies include different forms of Creutzfeldt-Jakob Disease (CJD), Kuru, Gerstmann-Sträussler-Scheinker Syndrome (GSS), and Fatal Familial Insomnia (FFI).

Iatrogenic transmission of spongiform encephalopathies has been reported. In sheep, scrapie has been accidentally transmitted by the use of Louping Ill vaccine prepared from pooled, formaldehyde treated ovine brain and spleen in which material from scrapie-infected sheep had been inadvertently incorporated. In man, cases of transmission of CJD have been reported which have been attributed to the parenteral administration of growth hormone and gonadotropin derived from human cadaveric pituitary glands. Cases of CJD have also been attributed to the use of contaminated instruments in brain surgery and with the transplantation of human dura mater and cornea.

Interspecies TSE transmission is restricted by a number of natural barriers, transmissibility being affected by the species of origin, the prion strain, dose, route of exposure and, in some species, the host allele of the PrP gene. Species barriers can be crossed under appropriate conditions.

Bovine spongiform encephalopathy (BSE) was first recognised in the United Kingdom in 1986 and a large number of cattle and individual herds have been affected. It is clear that BSE is a food borne disease associated with feeding meat and bone meal derived from TSE affected animals. Other countries have experienced cases of BSE, either in animals imported from the United Kingdom or in indigenous animals. There is convincing evidence to show that the variant form of CJD (vCJD) is caused by the agent which is responsible for BSE in cattle. Therefore, a cautious approach continues to be warranted if biological materials from species naturally affected by TSE diseases, especially bovine species, are used for the manufacture of medicinal products.

Scrapie occurs worldwide and has been reported in most European countries. It has the highest incidence in the United Kingdom. While humans have been exposed to naturally occurring scrapie for over 200 years, there is no epidemiological evidence directly linking scrapie to spongiform encephalopathies in humans. However, there remains a theoretical and currently unquantifiable risk that some BSE-contaminated protein supplement may have been fed to sheep. If such feed causes a recurrent BSE infection in sheep, it may be diagnosed as scrapie and might as such pose a risk of human TSEs. Further, it should also be assumed that any BSE agent introduced into the small ruminant population via contaminated feed is likely to be recycled and amplified.

1-2. REGULATORY COMPLIANCE

Risk assessment. Since the use of animal-derived materials is unavoidable for the production of some medicinal products and that complete elimination of risk at source is rarely possible, the measures taken to manage the risk of transmitting animal TSEs via medicinal products represent risk minimisation rather than risk elimination. Consequently, the basis for regulatory compliance should be based on a risk assessment, taking into consideration all pertinent factors as identified in this chapter (see below).

Legal Aspects. The note for guidance has been given the force of law by virtue of Annex I to European Parliament and Council Directives 2001/82/EC and 2001/83/EC

(as amended by Commission Directive 2003/63/EC⁽¹⁾), governing the veterinary and human medicinal products, respectively. These directives require that applicants for marketing authorisation for human and veterinary medicinal products must demonstrate that medicinal products are manufactured in accordance with the latest version of this note for guidance published in the *Official Journal of the European Union*. This is a continuing obligation after the marketing authorisation has been granted.

By definition, the principle of Specified Risk Materials as defined in Regulation (EC) No 999/2001 of the European Parliament and of the Council⁽²⁾ does not apply to medicinal products. The use of substances derived from high infectivity tissues must be fully justified following an appropriate benefit/risk evaluation (see further below).

The note for guidance should be read in conjunction with the various European Community legal instruments including Commission decisions progressively implemented since 1991. Where appropriate, references to these decisions are given in the text. Position statements and explanatory notes made by the Committee for Proprietary Medicinal Products (CPMP) and Committee for Veterinary Medicinal Products (CVMP) are still applicable for the purpose of regulatory compliance unless otherwise superseded by the note for guidance.

The general monograph *Products with risk of transmitting agents of animal spongiform encephalopathies* of the European Pharmacopoeia refers to this chapter, which is identical with the note for guidance. The monograph forms the basis for issuing Certificates of Suitability as a procedure for demonstrating TSE compliance for substances and materials used in the manufacture of human and veterinary medicinal products.

Clarification of note for guidance. As the scientific understanding of TSEs, especially the pathogenesis of the diseases, is evolving, from time to time CPMP and its Biotechnology Working Party in collaboration with CVMP and its Immunologicals Working Party may be required in the future to develop supplementary guidance in the form of position statements or explanatory notes for the purpose of clarifying the note for guidance. The supplementary guidance shall be published by the Commission and on the website of the European Agency for the Evaluation of Medicinal Products (EMA) and taken into consideration accordingly in the scope of the certification of the European Directorate for the Quality of Medicines (EDQM).

Implementation of the revised note for guidance. All authorised medicinal products in the European Union have demonstrated compliance with the note for guidance on minimising the risk of transmitting animal spongiform encephalopathy agents via human and veterinary medicinal products (EMA/410/01-Rev.1) in line with the legal requirement as inscribed in Annex I to Directive 2001/82/EC (veterinary medicines) or Directive 2001/83/EC as amended by Directive 2003/63/EC (medicines for human use). The revised note for guidance is to be applied prospectively, i.e. for all medicinal products that will be authorised or whose marketing authorisation will be renewed after the time of coming into operation of the revised note for guidance.

2. SCOPE OF THE CHAPTER

TSE-RELEVANT ANIMAL SPECIES

Cattle, sheep, goats and animals that are naturally susceptible to infection with transmissible spongiform encephalopathy agents or susceptible to infection through the oral route other than humans⁽³⁾ and non-human primates are defined as “TSE-relevant animal species”⁽⁴⁾.

MATERIALS

This chapter is concerned with materials derived from “TSE-relevant animal species” that are used for the preparation of:

- active substances,
- excipients and adjuvants,
- raw and starting materials and reagents used in production (e.g. bovine serum albumin; enzymes; culture media including those used to prepare working cell banks, or new master cell banks for medicinal products which are subject to a new marketing authorisation).

This chapter is also applicable to materials that come into direct contact with the equipment used in manufacture of the medicinal product or that come in contact with the medicinal product and therefore have the potential for contamination.

Materials used in the qualification of plant and equipment, such as culture media used in media fill experiments to validate the aseptic filling process, shall be considered in compliance with this chapter provided that the constituent or constituents are derived from tissues with no detectable infectivity (category C tissues), where the risk of cross-contamination with potentially infective tissues has been considered (see section 3-3) and where the materials are sourced from a GBR I/II country (see section 3-2). Such information shall be provided in the dossier for a marketing authorisation and verified during routine inspection for compliance with Good Manufacturing Practice (GMP).

Other materials such as cleaning agents, softeners and lubricants that come into contact with the medicinal product during its routine manufacture or in the finishing stage or in the primary packaging are considered in compliance with this chapter if they are derived from tallow under the conditions described in section 6.

SEED LOTS, CELL BANKS AND ROUTINE FERMENTATION/PRODUCTION⁽⁵⁾

For the purpose of regulatory compliance, master seeds or master cell banks in marketing authorisation applications lodged after 1 July 2000 (for human medicinal products) or 1 October 2000 (for veterinary medicinal products) are covered by the note for guidance.

Master seeds and master cell banks,

- for vaccine antigens;
- for a biotechnology-derived medicinal product within the meaning of Part A of the Annex to Council Regulation (EC) No 2309/93; and
- for other medicinal products using seed lots or cell banking systems in their manufacture,

that have already been approved for the manufacture of a constituent of an authorised medicinal product shall be considered in compliance with the note for guidance even if they are incorporated in marketing authorisation

(1) O.J. L 159, 27.06.2003, p. 46

(2) O.J. L 147, 31.05.2001, p. 1

(3) Regulatory guidance and position papers have been issued by the Committee for Proprietary Medicinal Products and its Biotechnology Working Party on human tissue derived medicinal products in relation with CJD and vCJD. Such guidance can be found on <http://www.emea.eu.int>.

(4) Pigs and birds, which are animal species of particular interest for the production of medicinal products, are not naturally susceptible to infection via the oral route. Therefore they are not TSE-relevant animal species within the meaning of this chapter. Also dogs, rabbits and fish are non TSE-relevant animal species within the meaning of this chapter.

(5) See also: Position paper on the assessment of the risk of transmission of animal spongiform encephalopathy agents by master seed materials used in the production of veterinary vaccines (EMA/CVMP/019/01-February 2001 adopted by the Committee for Veterinary Medicinal products (CVMP) in July 2001, Official Journal of the European Communities C 286 of 12 October 2001, p.12.

applications lodged after 1 July 2000 (for human medicinal products) or 1 October 2000 (for veterinary medicinal products).

Master cell banks and master seeds established before 1 July 2000 (for human medicinal products) or 1 October 2000 (for veterinary medicinal products), but not yet approved as a constituent of an authorised medicinal product shall demonstrate that they fulfil the requirements of the note for guidance. If, for some raw or starting materials or reagents used for the establishment of these cell banks or seeds, full documentary evidence is not/no longer available, the applicant should present a risk assessment as described in Section 4 of the note for guidance.

Established working seeds or cell banks used in the manufacture of medicinal products authorised before 1 July 2000 (human medicines) or 1 October 2000 (veterinary medicines), which have been subjected to a properly conducted risk assessment by a competent authority of the Member States or the EMEA and declared to be acceptable, shall also be considered compliant.

However, where materials derived from the “TSE-relevant animal species” are used in fermentation/routine production processes or in the establishment of working seeds and working cell banks, the applicant must demonstrate that they fulfil the requirements of the note for guidance.

3. GENERAL CONSIDERATIONS

3-1. SCIENTIFIC PRINCIPLES FOR MINIMISING RISK

When manufacturers have a choice, the use of materials from “non TSE-relevant animal species” or non-animal origin is preferred. The rationale for using materials derived from “TSE-relevant animal species” instead of materials from “non-TSE-relevant species” or of non-animal origin should be given. If materials from “TSE-relevant animal species” have to be used, consideration should be given to all the necessary measures to minimise the risk of transmission of TSE.

Readily applicable diagnostic tests for TSE infectivity *in vivo* are not yet available. Diagnosis is based on post-mortem confirmation of characteristic brain lesions by histopathology and/or detection of PrP^{Sc} by Western blot or immunoassay. The demonstration of infectivity by the inoculation of suspect tissue into target species or laboratory animals is also used for confirmation. However, due to the long incubation periods of all TSEs, results of *in vivo* tests are available only after months or years.

Several *in vitro* diagnostic tests capable of detecting PrP^{Sc} in brain samples from infected animals have been approved for use but in the main they are less sensitive than *in vivo* infectivity assays. Nonetheless, screening of source animals by *in vitro* tests may prevent the use of animals at late stages of incubation of the disease and may provide information about the epidemiological status of a given country or region.

Minimising the risks of transmission of TSE is based upon three complementary parameters:

- the source animals and their geographical origin,
- nature of animal material used in manufacture and any procedures in place to avoid cross-contamination with higher risk materials,
- production process(es) including the quality assurance system in place to ensure product consistency and traceability.

3-2. SOURCE ANIMALS

The source materials used for the production of materials for the manufacture of medicinal products shall be derived from animals fit for human consumption following ante- and post-mortem inspection in accordance with Community or equivalent (third country) conditions, except for materials derived from live animals, which should be found healthy after clinical examination.

3-2-1. Geographical sourcing

3-2-1-1. Bovine materials

There are currently two organisations involved in the assessment of the BSE status of a specified country or zone. Firstly, the Organisation Internationale des Epizooties (OIE)⁽⁶⁾ lays down the criteria for the assessment of the status of countries in the chapter of the International Animal Health Code on bovine spongiform encephalopathy. OIE also provides a list of notified BSE cases worldwide. Secondly, the European Commission Scientific Steering Committee (SSC)⁽⁷⁾ has established a system for classifying the countries according to their geographical BSE risk (GBR).

Regulation (EC) No 999/2001 of the European Parliament and of the Council laying down rules for the prevention, control and eradication of certain transmissible spongiform encephalopathies (TSE Regulation)⁽²⁾ entered into force on 1 July 2001. While medicinal products, medical devices and cosmetics are excluded from the scope of this Regulation, the principles for the determination of BSE status should be taken into account in the categorisation of the BSE status of a given country or region.

For the purposes of this chapter, the SSC GBR classification should be used as the indicator of the status of a given country. However, when countries are categorised according to Regulation (EC) No 999/2001, this categorisation should be used.

European Commission Scientific Steering Committee Classification

The European Scientific Steering Committee classification for geographical BSE risk (GBR) gives an indication of the level of likelihood of the presence of one or more cattle clinically or pre-clinically infected with BSE in a given country or region. A definition of the four categories is provided in the following Table.

GBR level	Presence of one or more cattle clinically or pre-clinically infected with BSE in a geographical region/country
I	Highly unlikely
II	Unlikely but not excluded
III	Likely but not confirmed or confirmed at a lower level
IV	Confirmed at a higher level ⁽¹⁾

(1) ≥ 100 cases/1 Million adult cattle per year

Reports of the GBR assessment of the countries are available on the SSC website⁽⁸⁾. If the BSE status of a country has not been classified by the SSC, a risk assessment shall be submitted taking into account the SSC criteria for the GBR classification.

Where there is a choice, animals should be sourced from countries with the lowest possible GBR level unless the use of material from higher GBR countries is justified. Some of the materials identified in Section 6, “Specific Conditions” can be sourced from GBR category III and, in some cases, category IV countries, provided that the controls and

(6) <http://www.oie.int>

(7) The Scientific Steering Committee established by Commission Decision 97/404/EC shall assist the Commission to obtain the best scientific advice available on matters relating to consumer health. Since May 2003, its tasks have been taken over by the European Food Safety Agency (EFSA): <http://www.efsa.eu.int>

(8) http://europa.eu.int/comm/food/fs/sc/ssc/outcome_en.html

requirements as specified in the relevant sections below are applied. Apart from these exceptions, animals must not be sourced from category IV countries, and justifications for the use of animals from category III countries must always be provided.

3-2-1-2. Sheep and goats (small ruminants)

Naturally occurring clinical scrapie cases have been reported in a number of countries worldwide. As BSE in sheep could possibly be mistaken for scrapie, as a precautionary measure, sourcing of materials derived from small ruminants shall take into account the prevalence of both BSE and scrapie in the country and the tissues from which the materials are derived.

The principles related to “BSE Negligible risk (closed) bovine herds” (see section 3-2-2) could equally be applied in the context of small ruminants in order to develop a framework to define the TSE status of a flock of small ruminants. For sheep, because of the concern over the possibility of BSE in sheep, the use of (a) genotype(s) shown to be resistant to BSE/scrapie infection shall be considered in establishing TSE free flocks. However, goats have not been studied sufficiently with regard to a genotype specific sensitivity.

Material of small ruminant origin should preferably be sourced from countries with a long history of absence of scrapie, such as New Zealand or Australia or from proven TSE-free flocks. Justification shall be required if the material is sourced from some other origin.

3-2-2. BSE negligible risk (closed) bovine herds. The safest sourcing is from countries where the presence of BSE is highly unlikely i.e. GBR I. Other countries may have or have had cases of BSE at some point in time and the practical concept of “Negligible risk (closed) bovine herds” has been developed by the SSC and endorsed by the CPMP and CVMP. Criteria for establishing and maintaining a “BSE negligible risk (closed) bovine herd” can be found in the SSC opinion of 22-23 July 1999⁽⁹⁾.

For the time being it is not possible to quantify the reduction of the geographical BSE risk for cattle from BSE negligible risk (closed) bovine herds. However, it is expected that this risk reduction is substantial. Therefore, sourcing from such closed bovine herds shall be considered in the risk assessment in conjunction with the GBR classification of the country.

3-3. ANIMAL PARTS, BODY FLUIDS AND SECRETIONS AS STARTING MATERIALS

In a TSE infected animal, different organs and secretions have different levels of infectivity⁽¹⁰⁾. The tables in the Annex of this chapter⁽¹¹⁾ summarise current data about the distribution of infectivity and PrP^{Sc} in cattle with BSE, and in sheep and goats with scrapie.

The information in the tables is based exclusively upon observations of naturally occurring disease or primary experimental infection by the oral route (in cattle) but does not include data on models using strains of TSE that have been adapted to experimental animals, because passaged strain phenotypes can differ significantly and unpredictably from those of naturally occurring disease. Because immunohistochemical and/or Western blot detection of misfolded host protein (PrP^{Sc}) have proven to be a surrogate marker of infectivity, PrP^{Sc} testing results have

been presented in parallel with bioassay data. Tissues are grouped into three major infectivity categories, irrespective of the stage of disease:

Category A	High-infectivity tissues central nervous system (CNS) tissues that attain a high titre of infectivity in the later stages of all TSEs, and certain tissues that are anatomically associated with the CNS
Category B	Lower-infectivity tissues peripheral tissues that have tested positive for infectivity and/or PrP ^{Sc} in at least one form of TSE
Category C	Tissues with no detectable infectivity tissues that have been examined for infectivity, without any infectivity detected, and/or PrP ^{Sc} , with negative results

Category A tissues and substances derived from them shall not be used in the manufacture of medicinal products, unless justified (see Section 5).

Although the category of lower risk tissues (category B tissues) almost certainly includes some (e.g. blood) with a lower risk than others (e.g. lymphoreticular tissues), the data about infectivity levels in these tissues are too limited to subdivide the category into different levels of risk. It is also evident that the placement of a given tissue in one or another category can be disease and species specific, and subject to revision as new data emerges.

For the risk assessment (see section 4), manufacturers and/or marketing authorisation holders/applicants shall take into account the tissue classification tables in the Annex to this chapter⁽¹²⁾.

The categories in the tables are only indicative and it is important to note the following points.

- In certain situations there could be cross-contamination of tissues of different categories of infectivity. The potential risk will be influenced by the circumstances in which tissues were removed, especially by contact of tissues with lower-infectivity tissues or no detectable infectivity (categories B and C tissues) with high-infectivity tissues (category A tissues). Thus, cross-contamination of some tissues may be increased if infected animals are slaughtered by penetrative brain stunning or if the brain and/or spinal cord is sawed. The risk of cross-contamination will be decreased if body fluids are collected with minimal damage to tissue and cellular components are removed, and if foetal blood is collected without contamination from other maternal or foetal tissues including placenta, amniotic and allantoic fluids. For certain tissues, it is very difficult or impossible to prevent cross-contamination with category A tissues (e.g. skull). This has to be considered in the risk assessment.
- For certain classes of substances the stunning/slaughtering techniques used may be important in minimising the potential risk⁽¹³⁾ because of the likelihood of disseminating the brain particles into the peripheral organs, particularly to the lungs. Stunning/slaughtering techniques should be described as well as the procedures to remove high infectivity tissues. The procedures to collect the animal tissues/organs to be used and the measures in place to avoid cross-contamination with a higher risk material must also be described in detail.

(9) SSC Scientific Opinion on the conditions related to “BSE Negligible Risk (Closed) Bovine Herds” adopted at the meeting of 22-23 July 1999. http://europa.eu.int/comm/food/fs/sc/ssc/out56_en.html

(10) If materials from “TSE-relevant animal species” have to be used, consideration should be given to use of materials of the lowest category of risk.

(11) The tissue classification tables are based upon the most recent WHO guidelines on transmissible spongiform encephalopathies in relation to biological and pharmaceutical products (February 2003) WHO/BCT/QSD/03.01.

(12) The introduction of the 3-category tissue classification system does not invalidate the risk-assessments based on the previously used 4-category tissue classification, performed for authorised medicinal products.

(13) SSC opinion on stunning methods and BSE risk (the risk of dissemination of brain particles into the blood and carcass when applying certain stunning methods), adopted at the meeting of 10-11 January 2002. http://europa.eu.int/comm/food/fs/sc/ssc/out245_en.pdf

- The risk of contamination of tissues and organs with BSE-infectivity potentially harboured in central nervous material as a consequence of the stunning method used for cattle slaughtering depends on the following factors:
 - the amount of BSE-infectivity in the brain of the slaughtered animal,
 - the extent of brain damage,
 - the dissemination of brain particles in the animal body.

These factors must be considered in conjunction with the GBR classification of the source animals, the age of the animals in the case of cattle and the post-mortem testing of the cattle using a validated method.

The underlying principles indicated above would be equally applicable to sheep and goats.

The risk posed by cross-contamination will be dependent on several complementary factors including:

- measures adopted to avoid contamination during collection of tissues (see above),
- level of contamination (amount of the contaminating tissue),
- amount and type of materials collected at the same time.

Manufacturers or the marketing authorisation holders/applicants should take into account the risk with respect to cross-contamination.

3.4. AGE OF ANIMALS

As the TSE infectivity accumulates in bovine animals over an incubation period of several years, it is prudent to source from young animals.

3.5. MANUFACTURING PROCESS

The assessment of the overall TSE risk reduction of a medicinal product shall take into account the control measures instituted with respect to:

- sourcing of the raw/starting materials, and
- the manufacturing process.

Controlled sourcing is a very important criterion in achieving acceptable safety of the product, due to the documented resistance of TSE agents to most inactivation procedures.

A quality assurance system, such as ISO 9000 certification, HACCP⁽¹⁴⁾ or GMP, must be put in place for monitoring the production process and for batch delineation (i.e. definition of batch, separation of batches, cleaning between batches). Procedures shall be put in place to ensure traceability as well as self-auditing and to auditing suppliers of raw/starting materials.

Certain production procedures may contribute considerably to the reduction of the risk of TSE contamination, e.g. procedures used in the manufacture of tallow derivatives (see section 6). As such rigorous processing cannot be applied to many products, processes involving physical removal, such as precipitation and filtration to remove prion-rich material, are likely to be more appropriate than chemical treatments. A description of the manufacturing process, including in-process controls applied, shall be presented and the steps that might contribute to reduction or elimination of TSE contamination should be discussed. Whenever different manufacturing sites are involved, the steps performed at each site shall be clearly identified. The measures in place in order to ensure traceability of every production batch to the source material should be described.

Cleaning process. Cleaning of process equipment may be difficult to validate for the elimination of TSE agents. It is reported that after exposure to high titre preparations of TSE

agent, detectable infectivity can remain bound to the surface of stainless steel. The removal of all adsorbed protein by the use of sodium hydroxide or chlorine releasing disinfectants (e.g. 20 000 ppm chlorine for 1 h) have been considered acceptable approaches where equipment that cannot be replaced has been exposed to potentially contaminated material. In the case of using category A materials in the manufacture of a product, dedicated equipment shall be used, unless otherwise justified.

If risk materials are used in the manufacture of a product, cleaning procedures, including control measures, shall be put in place in order to minimise the risk of cross-contamination between production batches. This is especially important if materials from different risk categories are handled in the same plant with the same equipment.

Removal/Inactivation validation. Validation studies of removal/inactivation procedures for TSEs are difficult to interpret. It is necessary to take into consideration the nature of the spiked material and its relevance to the natural situation, the design of the study (including scaling-down of processes) and the method of detection of the agent (*in vitro* or *in vivo* assay). Further research is needed to develop an understanding of the most appropriate “spike preparation” for validation studies. Therefore, validation studies are currently not generally required. However, if claims are made for the safety of the product with respect to TSEs based on the ability of manufacturing processes to remove or inactivate TSE agents, they must be substantiated by appropriate validation studies.

In addition to appropriate sourcing, manufacturers are encouraged to continue their investigations into removal and inactivation methods to identify steps/processes that would have benefit in assuring the removal or inactivation of TSE agents. In any event, a production process wherever possible shall be designed taking account of available information on methods which are thought to inactivate or remove TSE agents.

4. RISK ASSESSMENT OF MATERIALS OR SUBSTANCES USED IN THE MANUFACTURE AND PREPARATION OF A MEDICINAL PRODUCT IN THE CONTEXT OF REGULATORY COMPLIANCE

The assessment of the risk associated with TSE needs careful consideration of all of the parameters as outlined in section 3-1 (Scientific Principles for Minimising Risk).

As indicated in the introduction to this chapter, regulatory compliance is based on a favourable outcome from a risk assessment. The risk assessments, conducted by the manufacturers and/or the marketing authorisation holders or applicants for the different materials or substances from “TSE-relevant animal species” used in the manufacture of a medicinal product shall show that all TSE risk factors have been taken into account and, where possible, risk has been minimised by application of the principles described in this chapter. TSE Certificates of suitability issued by the EDQM may be used by the marketing authorisation holders or applicants as the basis of the risk assessments.

An overall risk assessment for the medicinal product, conducted by the marketing authorisation holders or applicants, shall take into account the risk assessments for all the different materials from “TSE-relevant animal species” and, where appropriate, TSE reduction or inactivation by the manufacturing steps of the active substance and/or finished product.

The final determination of regulatory compliance rests with the competent authority.

(14) Hazard Analysis Critical Control Point.

It is incumbent upon the manufacturers and/or the marketing authorisation holders or applicants for both human and veterinary medicinal products to select and justify the control measures for a given “TSE-relevant animal species” derivative, taking into account the state of the art of science and technology.

5. BENEFIT/RISK EVALUATION

In addition to the parameters as mentioned in sections 3 and 4, the acceptability of a particular medicinal product containing materials derived from a “TSE-relevant animal species”, or which as a result of manufacture could contain these materials, shall take into account the following factors:

- route of administration of the medicinal product,
- quantity of animal material used in the medicinal product,
- maximum therapeutic dosage (daily dose and duration of treatment),
- intended use of the medicinal product and its clinical benefit.

High-infectivity tissues (category A tissues) and substances derived thereof shall not be used in manufacture of medicinal products, their starting materials and intermediate products (including active substances, excipients and reagents), unless justified. A justification why no other materials can be used shall be provided. In these exceptional and justified circumstances, the use of high-infectivity tissues could be envisaged for the manufacture of active substances, when, after performing the risk assessment as described in Section 4 of this chapter, and taking into account the intended clinical use, a positive benefit/risk assessment can be presented by the marketing authorisation applicant. Substances from category A materials, if their use is justified, must be produced from animals of GBR I countries.

6. SPECIFIC CONSIDERATIONS

The following materials prepared from “TSE-relevant animal species” are considered in compliance with this chapter provided that they meet at least the conditions specified below. The relevant information or a certificate of suitability granted by the EDQM shall be provided by the marketing authorisation applicant/holder.

6-1. COLLAGEN

Collagen is a fibrous protein component of mammalian connective tissue.

For collagen, documentation to demonstrate compliance with this chapter needs to be provided taking into account the provisions listed in sections 3 to 5. In addition, consideration should be given to the following.

- For collagen produced from bones, the conditions specified for gelatin are applicable (see below).
- Collagen produced from tissues such as hides and skins do not usually present a measurable TSE risk provided that contamination with potentially infected materials, for example spillage of blood and/or central nervous tissues, is avoided during their procurement.

6-2. GELATIN

Gelatin is a natural, soluble protein, gelling or non-gelling, obtained by the partial hydrolysis of collagen produced from bones, hides and skins, tendons and sinews of animals.

For gelatin, documentation to demonstrate compliance with this chapter needs to be provided taking into account the provisions listed in sections 3 to 5. In addition, consideration should be given to the following.

The source material used

Gelatin used in medicinal products can be manufactured from bones or hides.

Hides as the starting material. On the basis of current knowledge, hides used for gelatin production represent a much safer source material as compared to bones. However, it is highly recommended that measures should be put in place to avoid cross-contamination with potentially infected materials during procurement.

Bones as the starting material. Where bones are used to manufacture gelatin, more stringent production conditions shall be applied (see below). In any case, the removal of skulls and spinal cords from the starting material is considered as a first precautionary measure which largely affects the safety of the product. As far as practicable, bones should be sourced from countries classified as GBR I and II. Bones from category GBR III countries can be used if the gelatin is manufactured under defined conditions as indicated below and if vertebrae from cattle over 12 months of age are removed from the raw/starting materials⁽¹⁵⁾.

Manufacturing methods

No specific measures with regard to the processing conditions are required for gelatin produced from hides provided that control measures are put in place to avoid cross-contamination both during the procurement of the hides and during the manufacturing process.

However, the mode of manufacture must be taken into account where bones are used as the starting material.

- Bones (including vertebrae) for the production of gelatin using acid treatment shall be sourced only from GBR category I or II countries. An additional alkaline treatment (pH 13, 1 h) of the bones/ossein may further increase the TSE safety of acid-derived bone gelatin.

For bones sourced from a GBR category III country, the alkaline process shall be applied. However, this manufacturing method is optional for bones coming from GBR category I and II countries.

- For a typical alkaline manufacturing process, bones are finely crushed, degreased with hot water and demineralised with dilute hydrochloric acid (at a minimum of 4 per cent and pH < 1.5) over a period of at least 2 days to produce the ossein. This is followed by an alkaline treatment with saturated lime solution (pH at least 12.5) for a period of at least 20 days. The gelatin is extracted, washed, filtered and concentrated. A “flash” heat treatment (sterilisation) step using 138-140 °C for 4 s is applied. Bovine hide gelatin can also be produced by the alkaline process. Bovine bones may also be treated by an acid process. The liming step is then replaced by an acid pre-treatment where the ossein is soaked overnight at pH < 4.

6-3. BOVINE BLOOD DERIVATIVES

Foetal bovine serum is commonly used in cell cultures. Foetal bovine serum should be obtained from fetuses harvested in abattoirs from healthy dams fit for human consumption and the womb should be completely removed and the foetal blood harvested in dedicated space or area by cardiac puncture into a closed collection system using aseptic technique.

New born calf serum is obtained from calves under 20 days old and calf serum from animals under the age of 12 months. In the case of donor bovine serum, given that it may be derived from animals less than 36 months old, the TSE status

(15) Regulation (EC) No 1774/2002 of the European Parliament and of the Council laying down health rules concerning animal by-products not intended for human consumption shall apply unless justified. Regarding the manufacturing of gelatin and collagen or import of raw material for such manufacturing for use in pharmaceutical products, only material from animals fit for human consumption shall be used. The use of vertebrae from such animals from category II countries, which according to the risk assessment is safe, shall continue to be allowed.

of the donor herd shall be well defined and documented. In all cases, serum shall be collected according to specified protocols by personnel trained in these procedures to avoid cross-contamination with higher risk tissues.

For bovine blood derivatives, documentation to demonstrate compliance with this chapter needs to be provided taking into account the provisions listed in sections 3 to 5. In addition, consideration should be given to the following.

Traceability

Traceability to the slaughterhouse must be assured for each batch of serum or plasma. Slaughterhouses must have available lists of farms from which the animals are originated. If serum is produced from living animals, records must be available for each serum batch which assures the traceability to the farms.

Geographical origin

Whilst tissue infectivity of BSE in cattle is more restricted than scrapie, as a precautionary measure bovine blood must be sourced from countries classified GBR I and II, unless otherwise justified.

Stunning methods

If it is sampled from slaughtered animals, the method of slaughter is of importance to assure the safety of the material. It has been demonstrated that stunning by captive bolt stunner with or without pithing as well as by pneumatic stunner, especially if it injects air, can destroy the brain and disseminate brain material into the blood stream. Negligible risk can be expected from a non-penetrative stunner and from electro-narcosis⁽¹⁶⁾. The stunning methods must therefore be described for the bovine blood collection process.

If sourcing is allowed from countries where cases of BSE have been detected (GBR III) a non-penetrative stunner shall be used for slaughter.

6-4. TALLOW DERIVATIVES

Tallow is fat obtained from tissues including subcutaneous, abdominal and inter-muscular areas and bones. Tallow used as the starting material for the manufacture of tallow derivatives shall be category 3 material or equivalent, as defined in Regulation (EC) No 1774/2002⁽¹⁷⁾ of the European Parliament and of the Council of 3 October 2002 laying down health rules concerning animal by-products not intended for human consumption.

Tallow derivatives, such as glycerol and fatty acids, manufactured from tallow by rigorous processes are thought unlikely to be infectious and they have been the subject of specific consideration by CPMP and CVMP. For this reason, such materials manufactured under the conditions at least as rigorous as those given below shall be considered in compliance for this chapter, irrespective of the geographical origin and the nature of the tissues from which tallow derivatives are derived. Examples of rigorous processes are:

- trans-esterification or hydrolysis at not less than 200 °C for not less than 20 min under pressure (glycerol, fatty acids and fatty acid esters production),
- saponification with 12 M NaOH (glycerol and soap production):
 - batch process: at not less than 95 °C for not less than 3 h,

- continuous process: at not less than 140 °C, under pressure for not less than 8 min, or equivalent,
- distillation at 200 °C.

Tallow derivatives manufactured according to these conditions are unlikely to present any TSE risk and shall therefore be considered compliant with this chapter.

Tallow derivatives produced using other conditions must demonstrate compliance with this chapter.

6-5. ANIMAL CHARCOAL

Animal charcoal is prepared by carbonisation of animal tissues, such as bones, using high temperature at > 800 °C. Unless otherwise justified, the starting material for the manufacture of animal charcoal shall be category 3 material or equivalent, as defined in Regulation (EC) No 1774/2002 of the European Parliament and of the Council of 3 October 2002 laying down health rules concerning animal by-products not intended for human consumption. Irrespective of the geographical origin and the nature of the tissue, for the purpose of regulatory compliance, animal charcoal shall be considered in compliance with this chapter.

Charcoal manufactured according to these conditions is unlikely to present any TSE risk and shall therefore be considered compliant with this chapter. Charcoal produced using other conditions must demonstrate compliance with this chapter.

6-6. MILK AND MILK DERIVATIVES

In the light of the current scientific knowledge and irrespective of the geographical origin, milk is unlikely to present any risk of TSE contamination.

Certain materials, including lactose, are extracted from whey, the spent liquid from cheese production following coagulation. Coagulation can involve the use of calf rennet, an extract from abomasum, or rennet derived from other ruminants. The CPMP/CVMP have performed a risk assessment for lactose and other whey derivatives produced using calf rennet and concluded that the TSE risk is negligible if the calf rennet is produced in accordance with the process described in the risk assessment report⁽¹⁸⁾. The conclusion was endorsed by the SSC⁽¹⁹⁾ which has also performed an assessment of the TSE risk of rennet in general⁽²⁰⁾.

Milk derivatives manufactured according to the conditions below are unlikely to present any TSE risk and shall therefore be considered compliant with this chapter.

- The milk is sourced from healthy animals in the same conditions as milk collected for human consumption, and
- no other ruminant materials, with the exception of calf rennet, are used in the preparation of such derivatives (e.g. pancreatic enzyme digests of casein).

Milk derivatives produced using other processes or rennet derived from other ruminant species must demonstrate compliance with this chapter.

6-7. WOOL DERIVATIVES

Derivatives of wool and hair of ruminants, such as lanolin and wool alcohols derived from hair shall be considered in compliance with this chapter, provided the wool and hair are sourced from live animals.

(16) SSC Opinion on stunning methods and BSE risk (The risk of dissemination of brain particles into the blood and carcass when applying certain stunning methods) adopted at the meeting on 10-11 January 2002. http://europa.eu.int/comm/food/fs/sc/ssc/out245_en.pdf

(17) OJ L 273, 10.10.2002, p. 1

(18) Committee for Proprietary Medicinal Products and its Biotechnology Working Party conducted a risk and regulatory assessment of lactose prepared using calf rennet. The risk assessment included the source of the animals, the excision of the abomasums and the availability of well-defined quality assurance procedures. The quality of any milk replacers used as feed for the animals from which abomasums are obtained is particularly important. The report can be found on <http://www.emea.eu.int>

(19) Provisional statement on the safety of calf-derived rennet for the manufacture of lactose. Adopted by the SSC at its meeting of 4-5 April 2002. (http://europa.eu.int/comm/food/fs/sc/ssc/out255_en.pdf)

(20) The SSC issued an opinion on the safety of animal rennet in regard to risks from animal TSE and BSE in particular, adopted at its meeting of 16 May 2002. (http://europa.eu.int/comm/food/fs/sc/ssc/out265_en.pdf)

Wool derivatives produced from wool which is sourced from slaughtered animals declared “fit for human consumption” and the manufacturing process in relation to pH, temperature and duration of treatment meets at least one of the stipulated processing conditions listed below are unlikely to present any TSE risk and shall therefore be considered compliant with this chapter.

- Treatment at pH ≥ 13 (initial; corresponding to a NaOH concentration of at least 0.1 M NaOH) at ≥ 60 °C for at least 1 h. This occurs normally during the reflux stage of the organic-alkaline treatment.
- Molecular distillation at ≥ 220 °C under reduced pressure.

Wool derivatives produced using other conditions must demonstrate compliance with this chapter.

6-8. AMINO ACIDS

Amino acids can be obtained by hydrolysis of materials from various sources.

Unless otherwise justified, the starting material for the manufacture of amino acids shall be category 3 material or equivalent, as defined in Regulation (EC) No 1774/2002 of the European Parliament and of the Council of 3 October 2002 laying down health rules concerning animal by-products not intended for human consumption.

Amino acids prepared using the following processing conditions, in accordance with Commission Decision 98/256/EC⁽²¹⁾ and Commission Decision 2001/376/EC⁽²²⁾, are unlikely to present any TSE risk and shall be considered compliant with this chapter:

- amino acids produced from hides and skins by a process which involves exposure of the material to a pH of 1 to 2, followed by a pH of > 11 , followed by heat treatment at 140 °C for 30 min at 3 bar,
- the resulting amino acids or peptides must be filtered after production, and
- analysis is performed using a validated and sensitive method to control any residual intact macromolecules, with an appropriate limit set.

Amino acids prepared using other conditions must demonstrate compliance with this chapter.

Annex: major categories of infectivity

The tables below are adapted from the *WHO Guideline on Transmissible Spongiform Encephalopathies in Relation to Biological and Pharmaceutical Products* (February 2003).

Data entries are shown as follows:

- + = presence of infectivity or PrP^{TSE}⁽²³⁾,
- = absence of detectable infectivity or PrP^{TSE},
- NT = not tested,
- ? = controversial or uncertain results.

(21) OJ L 113, 15.4.1998, p. 32

(22) OJ L 132, 15.5.2001, p. 17

(23) In the main body of this chapter the abnormal isoform of the prion protein is referred to as PrP^{Sc}. However, as these tables are transcribed directly from the WHO guideline mentioned above, the WHO nomenclature for the abnormal prion protein (PrP^{TSE}) has been maintained.

Category A: High-infectivity tissues

Tissues	Cattle BSE		Sheep and goats Scrapie	
	Infectivity ¹	PrP ^{TSE}	Infectivity ¹	PrP ^{TSE}
Brain	+	+	+	+
Spinal cord	+	+	+	+
Retina, Optic nerve	+	NT	NT	+
Spinal ganglia	+	NT	NT	+
Trigeminal ganglia	+	NT	NT	+
Pituitary gland ²	–	NT	+	NT
Dura mater ²	NT	NT	NT	NT

1. Infectivity bioassays of cattle tissues have been conducted in either cattle or mice (or both); and most bioassays of sheep and/or goat tissues have been conducted only in mice. In regard to sheep and goats not all results are consistent for both species.

2. No experimental data about infectivity in human pituitary gland or dura mater have been reported, but cadaveric dura mater patches, and growth hormone derived from cadaveric pituitaries have transmitted disease to scores of people and therefore must be included in the category of high-risk tissues.

Category B: Lower-infectivity tissues

Tissues	Cattle BSE		Sheep and goats Scrapie	
	Infectivity	PrP ^{TSE}	Infectivity	PrP ^{TSE}
Peripheral Nervous system				
Peripheral nerves	–	NT	+	NT
Enteric plexuses ¹	NT	+	NT	+
Lymphoreticular tissues				
Spleen	–	–	+	+
Lymph nodes	–	–	+	+
Tonsil	+	NT	+	+
Nictitating membrane	NT	–	NT	+
Thymus	–	NT	+	NT
Alimentary tract				
Esophagus	–	NT	NT	+
Fore-stomach ² (ruminants only)	–	NT	NT	+
Stomach/ abomasum ²	–	NT	NT	+
Duodenum	–	NT	NT	+
Jejunum	–	NT	NT	+
Ileum ³	+	+	+	+
Large intestine	–	NT	+	+
Reproductive tissues				
Placenta	–	NT	+	+
Other tissues				
Lung*	–	NT	–	NT
Liver	–	NT	+	NT

Tissues	Cattle BSE		Sheep and goats Scrapie	
	Infectivity	PrP ^{TSE}	Infectivity	PrP ^{TSE}
Kidney*	–	–	–	–
Adrenal	NT	NT	+	NT
Pancreas	–	NT	+	NT
Bone marrow	+	NT	+	NT
Blood vessels	–	NT	NT	+
Olfactory mucosa	–	NT	+	NT
Gingival tissue*	NT	NT	NT	NT
Salivary gland	–	NT	+	NT
Cornea ^{4*}	NT	NT	NT	NT
Body fluids				
CSF	–	NT	+	NT
Blood ⁵	–	NT	+	–

1. In cattle, limited to the distal ileum.

2. Ruminant forestomachs (reticulum, rumen, and omasum) are widely consumed, as is the true stomach (abomasum). The abomasum of cattle (and sometimes sheep) is also a source of rennet.

3. In cattle and sheep, only the distal ileum has been bioassayed for infectivity.

4. Because only one or two cases of CJD have been plausibly attributed to corneal transplants among hundreds of thousands of recipients, cornea is categorised as a lower-risk tissue; other anterior chamber tissues (lens, aqueous humor, iris, conjunctiva) have been tested with a negative result both in vCJD and other human TSEs, and there is no epidemiological evidence that they have been associated with iatrogenic disease transmission.

5. Early reports on the transmission of disease to rodents from the blood of patients with sCJD have not been confirmed, and evaluation of the ensemble of experimental and epidemiological data relevant to TSE transmission through blood, blood components, and therapeutic plasma products fails to suggest transmission from blood of patients with any form of “classical” TSE. Not enough data has accumulated to be able to make the same statement about blood from patients with vCJD. Foetal calf blood contains no detectable infectivity, but in genotypically susceptible sheep with natural scrapie or experimentally induced BSE, transfusion of large blood volumes has transmitted disease to healthy sheep. Infectivity has also been demonstrated in studies of rodent-adapted strains of TSE.

* These tissues have been classified under category B: Lower-infectivity tissues, because infectivity and/or PrP^{TSE} have been found in human CJD (vCJD or other).

Category C: Tissues with no detected infectivity

Tissues	Cattle BSE		Sheep and goats Scrapie	
	Infectivity	PrP ^{TSE}	Infectivity	PrP ^{TSE}
Reproductive tissues				
Testis	–	NT	–	NT
Prostate/Epididymis/Seminal vesicle	–	NT	–	NT

Body fluids, secretions and excretions				
Milk ³	–	NT	–	NT
Colostrum ⁴	NT	NT	–	NT
Cord blood ⁴	–	NT	NT	NT
Saliva	NT	NT	–	NT
Sweat	NT	NT	NT	NT
Tears	NT	NT	NT	NT
Nasal mucus	NT	NT	NT	NT
Urine ^{4,5}	–	NT	NT	NT
Faeces	–	NT	–	NT

1. Embryos from BSE-affected cattle have not transmitted disease to mice, but no infectivity measurements have been made on foetal calf tissues other than blood (negative mouse bioassay). Calves born of dams that received embryos from BSE-affected cattle have survived for observations periods of up to seven years, and examination of the brains of both the unaffected dams and their calves revealed no spongiform encephalopathy or PrP^{TSE}.

2. Intracerebral inoculation of muscle homogenates has not transmitted disease to 1) primates from humans with sCJD; 2) mice or cattle from cattle with BSE; and 3) mice from sheep and goats with natural or experimentally-induced scrapie. However, older reports described single instances of transmission from goat and hamster muscle, and a more recent report described transmission from the muscle of wild type and transgenic mice, but as each of these studies were conducted with passaged strains of TSE, their relevance to natural disease remains undetermined. A recent human case report described a patient with CJD and inclusion body myositis with abundant PrP^{TSE} in diseased muscle. After much deliberation, the committee nevertheless elected to retain muscle in the ‘no detected infectivity’ tissue category until more information about uncomplicated natural infections becomes available.

3. Evidence that infectivity is not present in milk includes temporo-spatial epidemiologic observations failing to detect maternal transmission; clinical observations of over a hundred calves nursed by infected cows that have not developed BSE; and experimental observations that milk from infected cows has not transmitted disease when administered intracerebrally or orally to mice. Experiments are in progress in which large volumes of milk from experimentally infected cows are concentrated and tested for the presence of PrP^{TSE}.

4. Single reports of transmission of CJD infectivity from human cord blood, colostrum, and urine have never been confirmed and are considered improbable.

5. A previously unreported PrP type, termed PrPⁿ, has been identified in the urine of sporadic and familial CJD patients, but its significance for transmission risk remains to be determined.

01/2005:50300

1. INTRODUCTION

This chapter provides guidance for the design of bioassays prescribed in the European Pharmacopoeia (Ph. Eur.) and for analysis of their results. It is intended for use by those whose primary training and responsibilities are not in statistics, but who have responsibility for analysis or interpretation of the results of these assays, often without the help and advice of a statistician. The methods of calculation described in this annex are not mandatory for the bioassays which themselves constitute a mandatory part of the Ph. Eur. Alternative methods may be used, provided that they are not less reliable than those described here. A wide range of computer software is available and may be useful depending on the facilities available to, and the expertise of, the analyst.

Professional advice should be obtained in situations where: a comprehensive treatment of design and analysis suitable for research or development of new products is required; the restrictions imposed on the assay design by this chapter are not satisfied, for example particular laboratory constraints may require customized assay designs, or equal numbers of equally spaced doses may not be suitable; analysis is required for extended non-linear dose-response curves, for example as may be encountered in immunoassays. An outline of extended dose-response curve analysis for one widely used model is nevertheless included in Section 3.4 and a simple example is given in Section 5.4.

1.1. GENERAL DESIGN AND PRECISION

Biological methods are described for the assay of certain substances and preparations whose potency cannot be adequately assured by chemical or physical analysis. The principle applied wherever possible throughout these assays is that of comparison with a standard preparation so as to determine how much of the substance to be examined produces the same biological effect as a given quantity, the *Unit*, of the standard preparation. It is an essential condition of such methods of biological assay that the tests on the standard preparation and on the substance to be examined be carried out at the same time and under identical conditions.

For certain assays (determination of virus titre for example) the potency of the test sample is not expressed relative to a standard. This type of assay is dealt with in Section 4.5.

Any estimate of potency derived from a biological assay is subject to random error due to the inherent variability of biological responses and calculations of error should be made, if possible, from the results of each assay, even when the official method of assay is used. Methods for the design of assays and the calculation of their errors are, therefore, described below. In every case, before a statistical method is adopted, a preliminary test is to be carried out with an appropriate number of assays, in order to ascertain the applicability of this method.

The confidence interval for the potency gives an indication of the precision with which the potency has been estimated in the assay. It is calculated with due regard to the experimental design and the sample size. The 95 per cent confidence interval is usually chosen in biological assays. Mathematical statistical methods are used to calculate these limits so as to warrant the statement that there is a 95 per cent probability that these limits include the true potency. Whether this

precision is acceptable to the European Pharmacopoeia depends on the requirements set in the monograph for the preparation concerned.

The terms “mean” and “standard deviation” are used here as defined in most current textbooks of biometry.

The terms “stated potency” or “labelled potency”, “assigned potency”, “assumed potency”, “potency ratio” and “estimated potency” are used in this section to indicate the following concepts:

- “stated potency” or “labelled potency”: in the case of a formulated product a nominal value assigned from knowledge of the potency of the bulk material; in the case of bulk material the potency estimated by the manufacturer;
- “assigned potency”: the potency of the standard preparation;
- “assumed potency”: the provisionally assigned potency of a preparation to be examined which forms the basis of calculating the doses that would be equipotent with the doses to be used of the standard preparation;
- “potency ratio” of an unknown preparation; the ratio of equipotent doses of the standard preparation and the unknown preparation under the conditions of the assay;
- “estimated potency”: the potency calculated from assay data.

Section 9 (Glossary of symbols) is a tabulation of the more important uses of symbols throughout this annex. Where the text refers to a symbol not shown in this section or uses a symbol to denote a different concept, this is defined in that part of the text.

2. RANDOMISATION AND INDEPENDENCE OF INDIVIDUAL TREATMENTS

The allocation of the different treatments to different experimental units (animals, tubes, etc.) should be made by some strictly random process. Any other choice of experimental conditions that is not deliberately allowed for in the experimental design should also be made randomly. Examples are the choice of positions for cages in a laboratory and the order in which treatments are administered. In particular, a group of animals receiving the same dose of any preparation should not be treated together (at the same time or in the same position) unless there is strong evidence that the relevant source of variation (for example, between times, or between positions) is negligible. Random allocations may be obtained from computers by using the built-in randomisation function. The analyst must check whether a different series of numbers is produced every time the function is started.

The preparations allocated to each experimental unit should be as independent as possible. Within each experimental group, the dilutions allocated to each treatment are not normally divisions of the same dose, but should be prepared individually. Without this precaution, the variability inherent in the preparation will not be fully represented in the experimental error variance. The result will be an under-estimation of the residual error leading to:

- 1) an unjustified increase in the stringency of the test for the analysis of variance (see Sections 3.2.3 and 3.2.4),

2) an under-estimation of the true confidence limits for the test which, as shown in Section 3.2.5, are calculated from the estimate of s^2 , the residual error mean square.

3. ASSAYS DEPENDING UPON QUANTITATIVE RESPONSES

3.1. STATISTICAL MODELS

3.1.1. GENERAL PRINCIPLES

The bioassays included in the Ph. Eur. have been conceived as “dilution assays”, which means that the unknown preparation to be assayed is supposed to contain the same active principle as the standard preparation, but in a different ratio of active and inert components. In such a case the unknown preparation may in theory be derived from the standard preparation by dilution with inert components. To check whether any particular assay may be regarded as a dilution assay, it is necessary to compare the dose-response relationships of the standard and unknown preparations. If these dose-response relationships differ significantly, then the theoretical dilution assay model is not valid. Significant differences in the dose-response relationships for the standard and unknown preparations may suggest that one of the preparations contains, in addition to the active principle, other components which are not inert but which influence the measured responses.

To make the effect of dilution in the theoretical model apparent, it is useful to transform the dose-response relationship to a linear function on the widest possible range of doses. 2 statistical models are of interest as models for the bioassays prescribed: the parallel-line model and the slope-ratio model.

The application of either is dependent on the fulfilment of the following conditions:

- 1) the different treatments have been randomly assigned to the experimental units,
- 2) the responses to each treatment are normally distributed,
- 3) the standard deviations of the responses within each treatment group of both standard and unknown preparations do not differ significantly from one another.

When an assay is being developed for use, the analyst has to determine that the data collected from many assays meet these theoretical conditions.

- Condition 1 can be fulfilled by an efficient use of Section 2.
- Condition 2 is an assumption which in practice is almost always fulfilled. Minor deviations from this assumption will in general not introduce serious flaws in the analysis as long as several replicates per treatment are included. In case of doubt, a test for deviations from normality (e.g. the Shapiro-Wilk⁽¹⁾ test) may be performed.
- Condition 3 can be checked with a test for homogeneity of variances (e.g. Bartlett's⁽²⁾ test, Cochran's⁽³⁾ test). Inspection of graphical representations of the data can also be very instructive for this purpose (see examples in Section 5).

When conditions 2 and/or 3 are not met, a transformation of the responses may bring a better fulfilment of these conditions. Examples are $\ln y$, $\sqrt{y}$, y^2 .

- Logarithmic transformation of the responses y to $\ln y$ can be useful when the homogeneity of variances is not satisfactory. It can also improve the normality if the distribution is skewed to the right.

- The transformation of y to $\sqrt{y}$ is useful when the observations follow a Poisson distribution i.e. when they are obtained by counting.
- The square transformation of y to y^2 can be useful if, for example, the dose is more likely to be proportional to the area of an inhibition zone rather than the measured diameter of that zone.

For some assays depending on quantitative responses, such as immunoassays or cell-based *in vitro* assays, a large number of doses is used. These doses give responses that completely span the possible response range and produce an extended non-linear dose-response curve. Such curves are typical for all bioassays, but for many assays the use of a large number of doses is not ethical (for example, *in vivo* assays) or practical, and the aims of the assay may be achieved with a limited number of doses. It is therefore customary to restrict doses to that part of the dose-response range which is linear under suitable transformation, so that the methods of Sections 3.2 or 3.3 apply. However, in some cases analysis of extended dose-response curves may be desirable. An outline of one model which may be used for such analysis is given in Section 3.4 and a simple example is shown in Section 5.4.

There is another category of assays in which the response cannot be measured in each experimental unit, but in which only the fraction of units responding to each treatment can be counted. This category is dealt with in Section 4.

3.1.2. ROUTINE ASSAYS

When an assay is in routine use, it is seldom possible to check systematically for conditions 1 to 3, because the limited number of observations per assay is likely to influence the sensitivity of the statistical tests. Fortunately, statisticians have shown that, in symmetrical balanced assays, small deviations from homogeneity of variance and normality do not seriously affect the assay results. The applicability of the statistical model needs to be questioned only if a series of assays shows doubtful validity. It may then be necessary to perform a new series of preliminary investigations as discussed in Section 3.1.1.

2 other necessary conditions depend on the statistical model to be used:

- for the parallel-line model:
 - 4A) the relationship between the logarithm of the dose and the response can be represented by a straight line over the range of doses used,
 - 5A) for any unknown preparation in the assay the straight line is parallel to that for the standard.
- for the slope-ratio model:
 - 4B) the relationship between the dose and the response can be represented by a straight line for each preparation in the assay over the range of doses used,
 - 5B) for any unknown preparation in the assay the straight line intersects the y -axis (at zero dose) at the same point as the straight line of the standard preparation (i.e. the response functions of all preparations in the assay must have the same intercept as the response function of the standard).

Conditions 4A and 4B can be verified only in assays in which at least 3 dilutions of each preparation have been tested. The use of an assay with only 1 or 2 dilutions may be justified when experience has shown that linearity and parallelism or equal intercept are regularly fulfilled.

(1) Wilk, M.B. and Shapiro, S.S. (1968). The joint assessment of normality of several independent samples, *Technometrics* 10, 825-839.

(2) Bartlett, M.S. (1937). Properties of sufficiency and statistical tests, *Proc. Roy. Soc. London, Series A* 160, 280-282.

(3) Cochran, W.G. (1951). Testing a linear relation among variances, *Biometrics* 7, 17-32.

After having collected the results of an assay, and before calculating the relative potency of each test sample, an analysis of variance is performed, in order to check whether conditions 4A and 5A (or 4B and 5B) are fulfilled. For this, the total sum of squares is subdivided into a certain number of sum of squares corresponding to each condition which has to be fulfilled. The remaining sum of squares represents the residual experimental error to which the absence or existence of the relevant sources of variation can be compared by a series of *F*-ratios.

When validity is established, the potency of each unknown relative to the standard may be calculated and expressed as a potency ratio or converted to some unit relevant to the preparation under test e.g. an International Unit. Confidence limits may also be estimated from each set of assay data.

Assays based on the parallel-line model are discussed in Section 3.2 and those based on the slope-ratio model in Section 3.3.

If any of the 5 conditions (1, 2, 3, 4A, 5A or 1, 2, 3, 4B, 5B) are not fulfilled, the methods of calculation described here are invalid and an investigation of the assay technique should be made.

The analyst should not adopt another transformation unless it is shown that non-fulfilment of the requirements is not incidental but is due to a systematic change in the experimental conditions. In this case, testing as described in Section 3.1.1 should be repeated before a new transformation is adopted for the routine assays.

Excess numbers of invalid assays due to non-parallelism or non-linearity, in a routine assay carried out to compare similar materials, are likely to reflect assay designs with inadequate replication. This inadequacy commonly results from incomplete recognition of all sources of variability affecting the assay, which can result in underestimation of the residual error leading to large *F*-ratios.

It is not always feasible to take account of all possible sources of variation within one single assay (e.g. day-to-day variation). In such a case, the confidence intervals from repeated assays on the same sample may not satisfactorily overlap, and care should be exercised in the interpretation of the individual confidence intervals. In order to obtain a more reliable estimate of the confidence interval it may be necessary to perform several independent assays and to combine these into one single potency estimate and confidence interval (see Section 6).

For the purpose of quality control of routine assays it is recommended to keep record of the estimates of the slope of regression and of the estimate of the residual error in control charts.

- An exceptionally high residual error may indicate some technical problem. This should be investigated and, if it can be made evident that something went wrong during the assay procedure, the assay should be repeated. An unusually high residual error may also indicate the presence of an occasional outlying or aberrant observation. A response that is questionable because of failure to comply with the procedure during the course of an assay is rejected. If an aberrant value is discovered after the responses have been recorded, but can then be traced to assay irregularities, omission may be justified. The arbitrary rejection or retention of an apparently aberrant response can be a serious source of bias. In general, the rejection of observations solely because a test for outliers is significant, is discouraged.

- An exceptionally low residual error may once in a while occur and cause the *F*-ratios to exceed the critical values. In such a case it may be justified to replace the residual error estimated from the individual assay, by an average residual error based on historical data recorded in the control charts.

3.1.3. CALCULATIONS AND RESTRICTIONS

According to general principles of good design the following 3 restrictions are normally imposed on the assay design. They have advantages both for ease of computation and for precision.

- Each preparation in the assay must be tested with the same number of dilutions.
- In the parallel-line model, the ratio of adjacent doses must be constant for all treatments in the assay; in the slope-ratio model, the interval between adjacent doses must be constant for all treatments in the assay.
- There must be an equal number of experimental units to each treatment.

If a design is used which meets these restrictions, the calculations are simple. The formulae are given in Sections 3.2 and 3.3. It is recommended to use software which has been developed for this special purpose. There are several programs in existence which can easily deal with all assay-designs described in the monographs. Not all programs may use the same formulae and algorithms, but they should all lead to the same results.

Assay designs not meeting the above mentioned restrictions may be both possible and correct, but the necessary formulae are too complicated to describe in this text. A brief description of methods for calculation is given in Section 7.1. These methods can also be used for the restricted designs, in which case they are equivalent with the simple formulae.

The formulae for the restricted designs given in this text may be used, for example, to create *ad hoc* programs in a spreadsheet. The examples in Section 5 can be used to clarify the statistics and to check whether such a program gives correct results.

3.2. THE PARALLEL-LINE MODEL

3.2.1. INTRODUCTION

The parallel-line model is illustrated in Figure 3.2.1-1. The logarithm of the doses are represented on the horizontal axis with the lowest concentration on the left and the highest concentration on the right. The responses are indicated on the vertical axis. The individual responses to each treatment are indicated with black dots. The 2 lines are the calculated $\ln(\text{dose})$ -response relationship for the standard and the unknown.

Note: the natural logarithm ($\ln$ or $\log_e$) is used throughout this text. Wherever the term “antilogarithm” is used, the quantity e^x is meant. However, the Briggs or “common” logarithm ($\log$ or $\log_{10}$) can equally well be used. In this case the corresponding antilogarithm is 10^x .

For a satisfactory assay the assumed potency of the test sample must be close to the true potency. On the basis of this assumed potency and the assigned potency of the standard, equipotent dilutions (if feasible) are prepared, i.e. corresponding doses of standard and unknown are expected to give the same response. If no information on the assumed potency is available, preliminary assays are carried out over a wide range of doses to determine the range where the curve is linear.

Figure 3.2.1-I. – *The parallel-line model for a 3 + 3 assay*
The more nearly correct the assumed potency of the unknown, the closer the 2 lines will be together, for they should give equal responses at equal doses. The horizontal distance between the lines represents the “true” potency of the unknown, relative to its assumed potency. The greater the distance between the 2 lines, the poorer the assumed potency of the unknown. If the line of the unknown is situated to the right of the standard, the assumed potency was overestimated, and the calculations will indicate an estimated potency lower than the assumed potency. Similarly, if the line of the unknown is situated to the left of the standard, the assumed potency was underestimated, and the calculations will indicate an estimated potency higher than the assumed potency.

3.2.2. ASSAY DESIGN

The following considerations will be useful in optimising the precision of the assay design:

- 1) the ratio between the slope and the residual error should be as large as possible,
- 2) the range of doses should be as large as possible,
- 3) the lines should be as close together as possible, i.e. the assumed potency should be a good estimate of the true potency.

The allocation of experimental units (animals, tubes, etc.) to different treatments may be made in various ways.

3.2.2.1. Completely randomised design

If the totality of experimental units appears to be reasonably homogeneous with no indication that variability in response will be smaller within certain recognisable sub-groups, the allocation of the units to the different treatments should be made randomly.

If units in sub-groups such as physical positions or experimental days are likely to be more homogeneous than the totality of the units, the precision of the assay may be increased by introducing one or more restrictions into the design. A careful distribution of the units over these restrictions permits irrelevant sources of variation to be eliminated.

3.2.2.2. Randomised block design

In this design it is possible to segregate an identifiable source of variation, such as the sensitivity variation between litters of experimental animals or the variation between Petri dishes in a diffusion microbiological assay. The design requires that every treatment be applied an equal number of times in

every block (litter or Petri dish) and is suitable only when the block is large enough to accommodate all treatments once. This is illustrated in Section 5.1.3. It is also possible to use a randomised design with repetitions. The treatments should be allocated randomly within each block. An algorithm to obtain random permutations is given in Section 8.5.

3.2.2.3. Latin square design

This design is appropriate when the response may be affected by two different sources of variation each of which can assume k different levels or positions. For example, in a plate assay of an antibiotic the treatments may be arranged in a $k \times k$ array on a large plate, each treatment occurring once in each row and each column. The design is suitable when the number of rows, the number of columns and the number of treatments are equal. Responses are recorded in a square format known as a Latin square. Variations due to differences in response among the k rows and among the k columns may be segregated, thus reducing the error. An example of a Latin square design is given in Section 5.1.2. An algorithm to obtain Latin squares is given in Section 8.6.

3.2.2.4. Cross-over design

This design is useful when the experiment can be sub-divided into blocks but it is possible to apply only 2 treatments to each block. For example, a block may be a single unit that can be tested on 2 occasions. The design is intended to increase precision by eliminating the effects of differences between units while balancing the effect of any difference between general levels of response at the 2 occasions. If 2 doses of a standard and of an unknown preparation are tested, this is known as a twin cross-over test.

The experiment is divided into 2 parts separated by a suitable time interval. Units are divided into 4 groups and each group receives 1 of the 4 treatments in the first part of the test. Units that received one preparation in the first part of the test receive the other preparation on the second occasion, and units receiving small doses in one part of the test receive large doses in the other. The arrangement of doses is shown in Table 3.2.2-I. An example can be found in Section 5.1.5.

Table 3.2.2-I. – *Arrangement of doses in cross-over design*

Group of units	Time I	Time II
1	S_1	T_2
2	S_2	T_1
3	T_1	S_2
4	T_2	S_1

3.2.3. ANALYSIS OF VARIANCE

This section gives formulae that are required to carry out the analysis of variance and will be more easily understood by reference to the worked examples in Section 5.1. Reference should also be made to the glossary of symbols (Section 9).

The formulae are appropriate for symmetrical assays where one or more preparations to be examined (T , U , etc.) are compared with a standard preparation (S). It is stressed that the formulae can only be used if the doses are equally spaced, if equal numbers of treatments per preparation are applied, and each treatment is applied an equal number of times. It should not be attempted to use the formulae in any other situation.

Apart from some adjustments to the error term, the basic analysis of data derived from an assay is the same for completely randomised, randomised block and Latin square designs. The formulae for cross-over tests do not entirely fit this scheme and these are incorporated into Example 5.1.5.

Having considered the points discussed in Section 3.1 and transformed the responses, if necessary, the values should be averaged over each treatment and each preparation, as shown in Table 3.2.3.-I. The linear contrasts, which relate to the slopes of the $\ln(\text{dose})$ -response lines, should also be formed. 3 additional formulae, which are necessary for the construction of the analysis of variance, are shown in Table 3.2.3.-II.

The total variation in response caused by the different treatments is now partitioned as shown in Table 3.2.3.-III the sums of squares being derived from the values obtained in Tables 3.2.3.-I and 3.2.3.-II. The sum of squares due to non-linearity can only be calculated if at least 3 doses per preparation are included in the assay.

The residual error of the assay is obtained by subtracting the variations allowed for in the design from the total variation in response (Table 3.2.3.-IV). In this table $\bar{y}$ represents the mean of all responses recorded in the assay. It should be noted that for a Latin square the number of replicate responses (n) is equal to the number of rows, columns or treatments (dh).

The analysis of variance is now completed as follows. Each sum of squares is divided by the corresponding number of degrees of freedom to give mean squares. The mean square for each variable to be tested is now expressed as a ratio to

the residual error (s^2) and the significance of these values (known as F -ratios) are assessed by use of Table 8.1 or a suitable sub-routine of a computer program.

3.2.4. TESTS OF VALIDITY

Assay results are said to be “statistically valid” if the outcome of the analysis of variance is as follows.

- 1) The linear regression term is significant, i.e. the calculated probability is less than 0.05. If this criterion is not met, it is not possible to calculate 95 per cent confidence limits.
- 2) The term for non-parallelism is not significant, i.e. the calculated probability is not less than 0.05. This indicates that condition 5A, Section 3.1, is satisfied;
- 3) The term for non-linearity is not significant, i.e. the calculated probability is not less than 0.05. This indicates that condition 4A, Section 3.1, is satisfied.

A significant deviation from parallelism in a multiple assay may be due to the inclusion in the assay-design of a preparation to be examined that gives an $\ln(\text{dose})$ -response line with a slope different from those for the other preparations. Instead of declaring the whole assay invalid, it may then be decided to eliminate all data relating to that preparation and to restart the analysis from the beginning.

When statistical validity is established, potencies and confidence limits may be estimated by the methods described in the next section.

Table 3.2.3.-I. – Formulae for parallel-line assays with d doses of each preparation

	Standard (S)	1 st Test sample (T)	2 nd Test sample (U, etc.)
Mean response lowest dose	S_1	T_1	U_1
Mean response 2 nd dose	S_2	T_2	U_2
...	...	...	...
Mean response highest dose	S_d	T_d	U_d
Total preparation	$P_S = S_1 + S_2 + \dots + S_d$	$P_T = T_1 + T_2 + \dots + T_d$	$P_U = \dots \text{etc.}$
Linear contrast	$L_S = 1S_1 + 2S_2 + \dots + dS_d - \frac{1}{2}(d+1)P_S$	$L_T = 1T_1 + 2T_2 + \dots + dT_d - \frac{1}{2}(d+1)P_T$	$L_U = \dots \text{etc.}$

Table 3.2.3.-II. – Additional formulae for the construction of the analysis of variance

$H_P = \frac{n}{d}$	$H_L = \frac{12n}{d^3 - d}$	$K = \frac{n(P_S + P_T + \dots)^2}{hd}$
---------------------	-----------------------------	---

Table 3.2.3.-III. – Formulae to calculate the sum of squares and degrees of freedom

Source of variation	Degrees of freedom (f)	Sum of squares
Preparations	$h - 1$	$SS_{\text{prep}} = H_P (P_S^2 + P_T^2 + \dots) - K$
Linear regression	1	$SS_{\text{reg}} = \frac{1}{h} H_L (L_S + L_T + \dots)^2$
Non-parallelism	$h - 1$	$SS_{\text{par}} = H_L (L_S^2 + L_T^2 + \dots) - SS_{\text{reg}}$
Non-linearity ^(*)	$h(d - 2)$	$SS_{\text{lin}} = SS_{\text{treat}} - SS_{\text{prep}} - SS_{\text{reg}} - SS_{\text{par}}$
Treatments	$hd - 1$	$SS_{\text{treat}} = n(S_1^2 + \dots + S_d^2 + T_1^2 + \dots + T_d^2 + \dots) - K$

Table 3.2.3-IV. – Estimation of the residual error

Source of variation	Degrees of freedom	Sum of squares
Blocks (rows)^(*)	$n - 1$	$SS_{\text{block}} = hd(R_1^2 + \dots + R_n^2) - K$
Columns^(**)	$n - 1$	$SS_{\text{col}} = hd(C_1^2 + \dots + C_n^2) - K$
Residual error^(***)	Completely randomised	$SS_{\text{res}} = SS_{\text{tot}} - SS_{\text{treat}}$
	Randomised block	$SS_{\text{res}} = SS_{\text{tot}} - SS_{\text{treat}} - SS_{\text{block}}$
	Latin square	$SS_{\text{res}} = SS_{\text{tot}} - SS_{\text{treat}} - SS_{\text{block}} - SS_{\text{col}}$
Total	$nhd - 1$	$SS_{\text{tot}} = \sum (y - \bar{y})^2$

(*) Not calculated for completely randomised designs
 (**) Only calculated for Latin square designs
 (***) Depends on the type of design

3.2.5. ESTIMATION OF POTENCY AND CONFIDENCE LIMITS

If I is the ln of the ratio between adjacent doses of any preparation, the common slope (b) for assays with d doses of each preparation is obtained from:

$$b = \frac{H_L(L_S + L_T + \dots)}{Inh} \quad (3.2.5-1)$$

and the logarithm of the potency ratio of a test preparation, for example T , is:

$$M'_T = \frac{P_T - P_S}{db} \quad (3.2.5-2)$$

The calculated potency is an estimate of the "true potency" of each unknown. Confidence limits may be calculated as the antilogarithms of:

$$CM'_T \pm \sqrt{(C-1)(CM_T'^2 + 2V)} \quad (3.2.5-3)$$

$$\text{where } C = \frac{SS_{\text{reg}}}{SS_{\text{reg}} - s^2t^2} \text{ and } V = \frac{SS_{\text{reg}}}{b^2dn}$$

The value of t may be obtained from Table 8.2 for $p = 0.05$ and degrees of freedom equal to the number of the degrees of freedom of the residual error. The estimated potency (R_T) and associated confidence limits are obtained by multiplying the values obtained by A_T after antilogarithms have been taken. If the stock solutions are not exactly equipotent on the basis of assigned and assumed potencies, a correction factor is necessary (See Examples 5.1.2 and 5.1.3).

3.2.6. MISSING VALUES

In a balanced assay, an accident totally unconnected with the applied treatments may lead to the loss of one or more responses, for example because an animal dies. If it is considered that the accident is in no way connected with the composition of the preparation administered, the exact calculations can still be performed but the formulae are necessarily more complicated and can only be given within the framework of general linear models (see Section 7.1). However, there exists an approximate method which keeps the simplicity of the balanced design by replacing the missing response by a calculated value. The loss of information is taken into account by diminishing the degrees of freedom for the total sum of squares and for the residual error by the number of missing values and using one of the formulae below for the missing values. It should be borne in mind that this is only an approximate method, and that the exact method is to be preferred.

If more than one observation is missing, the same formulae can be used. The procedure is to make a rough guess at all the missing values except one, and to use the proper formula for this one, using all the remaining values including the rough guesses. Fill in the calculated value. Continue by

similarly calculating a value for the first rough guess. After calculating all the missing values in this way the whole cycle is repeated from the beginning, each calculation using the most recent guessed or calculated value for every response to which the formula is being applied. This continues until 2 consecutive cycles give the same values; convergence is usually rapid.

Provided that the number of values replaced is small relative to the total number of observations in the full experiment (say less than 5 per cent), the approximation implied in this replacement and reduction of degrees of freedom by the number of missing values so replaced is usually fairly satisfactory. The analysis should be interpreted with great care however, especially if there is a preponderance of missing values in one treatment or block, and a biometrician should be consulted if any unusual features are encountered. Replacing missing values in a test without replication is a particularly delicate operation.

Completely randomised design

In a completely randomised assay the missing value can be replaced by the arithmetic mean of the other responses to the same treatment.

Randomised block design

The missing value is obtained using the equation:

$$y' = \frac{nB' + kT' - G'}{(n-1)(k-1)} \quad (3.2.6-1)$$

where B' is the sum of the responses in the block containing the missing value, T' the corresponding treatment total and G' is the sum of all responses recorded in the assay.

Latin square design

The missing value y' is obtained from:

$$y' = \frac{k(B' + C' + T') - 2G'}{(k-1)(k-2)} \quad (3.2.6-2)$$

where B' and C' are the sums of the responses in the row and column containing the missing value. In this case $k = n$.

Cross-over design

If an accident leading to loss of values occurs in a cross-over design, a book on statistics should be consulted (e.g. D.J. Finney, see Section 10), because the appropriate formulae depend upon the particular treatment combinations.

3.3. THE SLOPE-RATIO MODEL

3.3.1. INTRODUCTION

This model is suitable, for example, for some microbiological assays when the independent variable is the concentration of an essential growth factor below the optimal concentration of the medium. The slope-ratio model is illustrated in Figure 3.3.1-I.

Figure 3.3.1.-I. – The slope-ratio model for a $2 \times 3 + 1$ assay

The doses are represented on the horizontal axis with zero concentration on the left and the highest concentration on the right. The responses are indicated on the vertical axis. The individual responses to each treatment are indicated with black dots. The 2 lines are the calculated dose-response relationship for the standard and the unknown under the assumption that they intersect each other at zero-dose. Unlike the parallel-line model, the doses are not transformed to logarithms.

Just as in the case of an assay based on the parallel-line model, it is important that the assumed potency is close to the true potency, and to prepare equipotent dilutions of the test preparations and the standard (if feasible). The more nearly correct the assumed potency, the closer the 2 lines will be together. The ratio of the slopes represents the “true” potency of the unknown, relative to its assumed potency. If the slope of the unknown preparation is steeper than that of the standard, the potency was underestimated and the calculations will indicate an estimated potency higher than the assumed potency. Similarly, if the slope of the unknown is less steep than that of the standard, the potency was overestimated and the calculations will result in an estimated potency lower than the assumed potency.

In setting up an experiment, all responses should be examined for the fulfilment of the conditions 1, 2 and 3 in Section 3.1. The analysis of variance to be performed in routine is described in Section 3.3.3 so that compliance with conditions 4B and 5B of Section 3.1 may be examined.

3.3.2. ASSAY DESIGN

The use of the statistical analysis presented below imposes the following restrictions on the assay:

- the standard and the test preparations must be tested with the same number of equally spaced dilutions,
- an extra group of experimental units receiving no treatment may be tested (the blanks),
- there must be an equal number of experimental units to each treatment.

As already remarked in Section 3.1.3, assay designs not meeting these restrictions may be both possible and correct, but the simple statistical analyses presented here are no longer applicable and either expert advice should be sought or suitable software should be used.

A design with 2 doses per preparation and 1 blank, the “common zero ($2h + 1$)-design”, is usually preferred, since it gives the highest precision combined with the possibility to check validity within the constraints mentioned above. However, a linear relationship cannot always be assumed to be valid down to zero-dose. With a slight loss of precision a design without blanks may be adopted. In this case 3 doses per preparation, the “common zero ($3h$)-design”, are preferred to 2 doses per preparation. The doses are thus given as follows:

- the standard is given in a high dose, near to but not exceeding the highest dose giving a mean response on the straight portion of the dose-response line,
- the other doses are uniformly spaced between the highest dose and zero dose,
- the test preparations are given in corresponding doses based on the assumed potency of the material.

A completely randomised, a randomised block or a Latin square design may be used, such as described in Section 3.2.2. The use of any of these designs necessitates an adjustment to the error sum of squares as described for assays based on the parallel-line model. The analysis of an assay of one or more test preparations against a standard is described below.

3.3.3. ANALYSIS OF VARIANCE

3.3.3.1. The ($hd + 1$)-design

The responses are verified as described in Section 3.1 and, if necessary, transformed. The responses are then averaged over each treatment and each preparation as shown in Table 3.3.3.1.-I. Additionally, the mean response for blanks (B) is calculated.

The sums of squares in the analysis of variance are calculated as shown in Tables 3.3.3.1.-I to 3.3.3.1.-III. The sum of squares due to non-linearity can only be calculated if at least 3 doses of each preparation have been included in the assay. The residual error is obtained by subtracting the variations allowed for in the design from the total variation in response (Table 3.3.3.1.-IV).

The analysis of variance is now completed as follows. Each sum of squares is divided by the corresponding number of degrees of freedom to give mean squares. The mean square for each variable to be tested is now expressed as a ratio to the residual error (s^2) and the significance of these values (known as F -ratios) are assessed by use of Table 8.1 or a suitable sub-routine of a computer program.

3.3.3.2. The (hd)-design

The formulae are basically the same as those for the ($hd + 1$)-design, but there are some slight differences.

- B is discarded from all formulae.
- $$K = \frac{n(P_S + P_T + \dots)^2}{hd}$$
- SS_{blank} is removed from the analysis of variance.
- The number of degrees of freedom for treatments becomes $hd - 1$.
- The number of degrees of freedom of the residual error and the total variance is calculated as described for the parallel-line model (see Table 3.2.3.-IV).

Validity of the assay, potency and confidence interval are found as described in Sections 3.3.4 and 3.3.5.

Table 3.3.3.1-I. – *Formulae for slope-ratio assays with d doses of each preparation and a blank*

	Standard (S)	1st Test sample (T)	2nd Test sample (U, etc.)
Mean response lowest dose	S_1	T_1	U_1
Mean response 2 nd dose	S_2	T_2	U_2
...	...	...	...
Mean response highest dose	S_d	T_d	U_d
Total preparation	$P_S = S_1 + S_2 + \dots + S_d$	$P_T = T_1 + T_2 + \dots + T_d$	$P_U = \dots$
Linear product	$L_S = 1S_1 + 2S_2 + \dots + dS_d$	$L_T = 1T_1 + 2T_2 + \dots + dT_d$	$L_U = \dots$
Intercept value	$a_S = (4d + 2)P_S - 6L_S$	$a_T = (4d + 2)P_T - 6L_T$	$a_U = \dots$
Slope value	$b_S = 2L_S - (d + 1)P_S$	$b_T = 2L_T - (d + 1)P_T$	$b_U = \dots$
Treatment value	$G_S = S_1^2 + \dots + S_d^2$	$G_T = T_1^2 + \dots + T_d^2$	$G_U = \dots$
Non-linearity(*)	$J_S = G_S - \frac{P_S^2}{d} - \frac{3b_S^2}{d^3 - d}$	$J_T = G_T - \frac{P_T^2}{d} - \frac{3b_T^2}{d^3 - d}$	$J_U = \dots$

(*) Not calculated for two-dose assays

Table 3.3.3.1-II. – *Additional formulae for the construction of the analysis of variance*

$H_B = \frac{nhd^2 - nhd}{hd^2 - hd + 4d + 2}$	$H_I = \frac{n}{4d^3 - 2d^2 - 2d}$	$a = \frac{a_S + a_T + \dots}{h(d^2 - d)}$	$K = \frac{n(B + P_S + P_T + \dots)^2}{hd + 1}$
--	------------------------------------	--	---

Table 3.3.3.1-III. – *Formulae to calculate the sum of squares and degrees of freedom*

Source of variation	Degrees of freedom (f)	Sum of squares
Regression	h	$SS_{\text{reg}} = SS_{\text{treat}} - SS_{\text{blank}} - SS_{\text{int}} - SS_{\text{lin}}$
Blanks	1	$SS_{\text{blank}} = H_B(B - a)^2$
Intersection	$h - 1$	$SS_{\text{int}} = H_I((a_S^2 + a_T^2 + \dots) - h(d^2 - d)^2 a^2)$
Non-linearity(*)	$h(d - 2)$	$SS_{\text{lin}} = n(J_S + J_T + \dots)$
Treatments	hd	$SS_{\text{treat}} = n(B^2 + G_S + G_T + \dots) - K$

(*) Not calculated for two-dose assays

3.3.4. TESTS OF VALIDITY

Assay results are said to be “statistically valid” if the outcome of the analysis of variance is as follows:

- 1) the variation due to blanks in $(hd + 1)$ -designs is not significant, i.e. the calculated probability is not smaller than 0.05. This indicates that the responses of the blanks do not significantly differ from the common intercept and the linear relationship is valid down to zero dose;
- 2) the variation due to intersection is not significant, i.e. the calculated probability is not less than 0.05. This indicates that condition 5B, Section 3.1 is satisfied;
- 3) in assays including at least 3 doses per preparation, the variation due to non-linearity is not significant, i.e. the calculated probability is not less than 0.05. This indicates that condition 4B, Section 3.1 is satisfied.

A significant variation due to blanks indicates that the hypothesis of linearity is not valid near zero dose. If this is likely to be systematic rather than incidental for the type of assay, the (hd) -design is more appropriate. Any response to blanks should then be disregarded.

When these tests indicate that the assay is valid, the potency is calculated with its confidence limits as described in Section 3.3.5.

3.3.5. ESTIMATION OF POTENCY AND CONFIDENCE LIMITS

3.3.5.1. The $(hd + 1)$ -design

The common intersection a' of the preparations can be calculated from:

$$a' = \frac{(2d + 1)B + (2d - 3)ha}{h(2d - 3) + 2d + 1} \quad (3.3.5.1-1)$$

The slope of the standard, and similarly for each of the other preparations, is calculated from:

$$b'_S = \frac{6L_S - 3d(d + 1)a'}{2d^3 + 3d^2 + d} \quad (3.3.5.1-2)$$

The potency ratio of each of the test preparations can now be calculated from:

Table 3.3.3.1-IV. – Estimation of the residual error

Source of variation	Degrees of freedom	Sum of squares	
Blocks (rows) ^(*)	$n - 1$	$SS_{block} = hd (R_1^2 + ... + R_n^2) - K$	
Columns ^(**)	$n - 1$	$SS_{col} = hd (C_1^2 + ... + C_n^2) - K$	
Residual error ^(***)	Completely randomised $(hd + 1) (n - 1)$	$SS_{res} = SS_{tot} - SS_{treat}$	
		Randomised block $hd (n - 1)$	$SS_{res} = SS_{tot} - SS_{treat} - SS_{block}$
		Latin square $(hd - 1) (n - 1)$	$SS_{res} = SS_{tot} - SS_{treat} - SS_{block} - SS_{col}$
Total	$nhd + n - 1$	$SS_{tot} = \sum (y - \bar{y})^2$	

(*) Not calculated for completely randomised designs

(**) Only calculated for Latin square designs

(***) Depends on the type of design

$$R'_T = \frac{b'_T}{b'_S} \quad (3.3.5.1.3)$$

which has to be multiplied by A_r , the assumed potency of the test preparation, in order to find the estimated potency R_r . If the step between adjacent doses was not identical for the standard and the test preparation, the potency has to be multiplied by I_s/I_r . Note that, unlike the parallel-line analysis, no antilogarithms are calculated.

The confidence interval for R'_r is calculated from:

$$CR'_T - K' \pm \sqrt{(C - 1)(CR'^2_T + 1) + K'(K' - 2CR'_T)} \quad (3.3.5.1.4)$$

$$\text{where } C = \frac{b'^2_S}{b'^2_S - s^2 t^2 V_1} \text{ and } K' = (C - 1)V_2$$

V_1 and V_2 are related to the variance and covariance of the numerator and denominator of R_r . They can be obtained from:

$$V_1 = \frac{6}{n(2d + 1)} \left(\frac{1}{d(d + 1)} + \frac{3}{2(2d + 1) + hd(d - 1)} \right) \quad (3.3.5.1.5)$$

$$V_2 = \frac{3d(d + 1)}{(3d + 1)(d + 2) + hd(d - 1)} \quad (3.3.5.1.6)$$

The confidence limits are multiplied by A_r , and if necessary by I_s/I_r .

3.3.5.2. The (hd) -design

The formulae are the same as for the $(hd + 1)$ -design, with the following modifications:

$$a' = a \quad (3.3.5.2.1)$$

$$V_1 = \frac{6}{nd(2d + 1)} \left(\frac{1}{d + 1} + \frac{3}{h(d - 1)} \right) \quad (3.3.5.2.2)$$

$$V_2 = \frac{3(d + 1)}{3(d + 1) + h(d - 1)} \quad (3.3.5.2.3)$$

3.4. EXTENDED SIGMOID DOSE-RESPONSE CURVES

This model is suitable, for example, for some immunoassays when analysis is required of extended sigmoid dose-response curves. This model is illustrated in Figure 3.4-I.

Figure 3.4-I. – The four-parameter logistic curve model
 The logarithms of the doses are represented on the horizontal axis with the lowest concentration on the left and the highest concentration on the right. The responses are indicated on the vertical axis. The individual responses to each treatment are indicated with black dots. The 2 curves are the calculated $\ln(\text{dose})$ -response relationship for the standard and the test preparation.

The general shape of the curves can usually be described by a logistic function but other shapes are also possible. Each curve can be characterised by 4 parameters: The upper asymptote (α), the lower asymptote (δ), the slope-factor (β), and the horizontal location (γ). This model is therefore often referred to as a four-parameter model. A mathematical representation of the $\ln(\text{dose})$ -response curve is:

$$u = \delta + \frac{\alpha - \delta}{1 + e^{-\beta(x - \gamma)}}$$

For a valid assay it is necessary that the curves of the standard and the test preparations have the same slope-factor, and the same maximum and minimum response level at the extreme parts. Only the horizontal location (γ) of the curves may be different. The horizontal distance between the curves is related to the “true” potency of the unknown. If the assay is used routinely, it may be sufficient to test the condition of equal upper and lower response levels when the assay is

developed, and then to retest this condition directly only at suitable intervals or when there are changes in materials or assay conditions.

The maximum-likelihood estimates of the parameters and their confidence intervals can be obtained with suitable computer programs. These computer programs may include some statistical tests reflecting validity. For example, if the maximum likelihood estimation shows significant deviations from the fitted model under the assumed conditions of equal upper and lower asymptotes and slopes, then one or all of these conditions may not be satisfied.

The logistic model raises a number of statistical problems which may require different solutions for different types of assays, and no simple summary is possible. A wide variety of possible approaches is described in the relevant literature. Professional advice is therefore recommended for this type of analysis. A simple example is nevertheless included in Section 5.4 to illustrate a “possible” way to analyse the data presented. A short discussion of alternative approaches and other statistical considerations is given in Section 7.5.

If professional advice or suitable software is not available, alternative approaches are possible: 1) if “reasonable” estimates of the upper limit (α) and lower limit (δ) are available, select for all preparations the doses with mean of the responses (u) falling between approximately 20 per cent and 80 per cent of the limits, transform responses of the selected doses to $y = \ln \left(\frac{u - \delta}{\alpha - u} \right)$ and use the parallel line model (Section 3.2) for the analysis; 2) select a range of doses for which the responses (u) or suitably transformed responses, for example $\ln(u)$, are approximately linear when plotted against $\ln(\text{dose})$; the parallel line model (Section 3.2) may then be used for analysis.

4. ASSAYS DEPENDING UPON QUANTAL RESPONSES

4.1. INTRODUCTION

In certain assays it is impossible or excessively laborious to measure the effect on each experimental unit on a quantitative scale. Instead, an effect such as death or hypoglycaemic symptoms may be observed as either occurring or not occurring in each unit, and the result depends on the number of units in which it occurs. Such assays are called quantal or all-or-none.

The situation is very similar to that described for quantitative assays in Section 3.1, but in place of n separate responses to each treatment a single value is recorded, i.e. the fraction of units in each treatment group showing a response. When these fractions are plotted against the logarithms of the doses the resulting curve will tend to be sigmoid (S-shaped) rather than linear. A mathematical function that represents this sigmoid curvature is used to estimate the dose-response curve. The most commonly used function is the cumulative normal distribution function. This function has some theoretical merit, and is perhaps the best choice if the response is a reflection of the tolerance of the units. If the response is more likely to depend upon a process of growth, the logistic distribution model is preferred, although the difference in outcome between the 2 models is usually very small.

The maximum likelihood estimators of the slope and location of the curves can be found only by applying an iterative procedure. There are many procedures which lead to the same outcome, but they differ in efficiency due to the speed of convergence. One of the most rapid methods is direct

optimisation of the maximum-likelihood function (see Section 7.1), which can easily be performed with computer programs having a built-in procedure for this purpose. Unfortunately, most of these procedures do not yield an estimate of the confidence interval, and the technique to obtain it is too complicated to describe here. The technique described below is not the most rapid, but has been chosen for its simplicity compared to the alternatives. It can be used for assays in which one or more test preparations are compared to a standard. Furthermore, the following conditions must be fulfilled:

- 1) the relationship between the logarithm of the dose and the response can be represented by a cumulative normal distribution curve,
- 2) the curves for the standard and the test preparation are parallel, i.e. they are identically shaped and may only differ in their horizontal location,
- 3) in theory, there is no natural response to extremely low doses and no natural non-response to extremely high doses.

4.2. THE PROBIT METHOD

The sigmoid curve can be made linear by replacing each response, i.e. the fraction of positive responses per group, by the corresponding value of the cumulative standard normal distribution. This value, often referred to as “normit”, ranges theoretically from $-\infty$ to $+\infty$. In the past it was proposed to add 5 to each normit to obtain “probits”. This facilitated the hand-performed calculations because negative values were avoided. With the arrival of computers the need to add 5 to the normits has disappeared. The term “normit method” would therefore be better for the method described below. However, since the term “probit analysis” is so widely spread, the term will, for historical reasons, be maintained in this text.

Once the responses have been linearised, it should be possible to apply the parallel-line analysis as described in Section 3.2. Unfortunately, the validity condition of homogeneity of variance for each dose is not fulfilled. The variance is minimal at normit = 0 and increases for positive and negative values of the normit. It is therefore necessary to give more weight to responses in the middle part of the curve, and less weight to the more extreme parts of the curve. This method, the analysis of variance, and the estimation of the potency and confidence interval are described below.

4.2.1. TABULATION OF THE RESULTS

Table 4.2.1-I is used to enter the data into the columns indicated by numbers:

- (1) the dose of the standard or the test preparation,
- (2) the number n of units submitted to that treatment,
- (3) the number of units r giving a positive response to the treatment,
- (4) the logarithm x of the dose,
- (5) the fraction $p = r/n$ of positive responses per group.

The first cycle starts here.

- (6) column Y is filled with zeros at the first iteration,
 - (7) the corresponding value $\Phi = \Phi(Y)$ of the cumulative standard normal distribution function (see also Table 8.4).
- The columns (8) to (10) are calculated with the following formulae:

$$(8) \quad Z = \frac{e^{-Y^2/2}}{\sqrt{2\pi}} \quad (4.2.1-1)$$

$$(9) \quad y = Y + \frac{p - \Phi}{Z} \quad (4.2.1-2)$$

$$(10) \quad w = \frac{nZ^2}{\Phi - \Phi^2} \quad (4.2.1-3)$$

The columns (11) to (15) can easily be calculated from columns (4), (9) and (10) as wx , wy , wx^2 , wy^2 and wxy respectively, and the sum (Σ) of each of the columns (10) to (15) is calculated separately for each of the preparations.

The sums calculated in Table 4.2.1-I are transferred to columns (1) to (6) of Table 4.2.1-II and 6 additional columns (7) to (12) are calculated as follows:

$$(7) \quad S_{xx} = \sum wx^2 - \frac{(\sum wx)^2}{\sum w} \quad (4.2.1-4)$$

$$(8) \quad S_{xy} = \sum wxy - \frac{(\sum wx)(\sum wy)}{\sum w} \quad (4.2.1-5)$$

$$(9) \quad S_{yy} = \sum wy^2 - \frac{(\sum wy)^2}{\sum w} \quad (4.2.1-6)$$

$$(10) \quad \bar{x} = \frac{\sum wx}{\sum w} \quad (4.2.1-7)$$

$$(11) \quad \bar{y} = \frac{\sum wy}{\sum w} \quad (4.2.1-8)$$

The common slope b can now be obtained as:

$$b = \frac{\sum S_{xy}}{\sum S_{xx}} \quad (4.2.1-9)$$

and the intercept a of the standard, and similarly for the test preparations is obtained as:

$$(12) \quad a = \bar{y} - b\bar{x} \quad (4.2.1-10)$$

Column (6) of the first working table can now be replaced by $Y = a + bx$ and the cycle is repeated until the difference between 2 cycles has become small (e.g. the maximum difference of Y between 2 consecutive cycles is smaller than 10^{-8}).

4.2.2. TESTS OF VALIDITY

Before calculating the potencies and confidence intervals, validity of the assay must be assessed. If at least 3 doses for each preparation have been included, the deviations from linearity can be measured as follows: add a 13th column to Table 4.2.1-II and fill it with:

$$S_{yy} - \frac{S_{xy}^2}{S_{xx}} \quad (4.2.2-1)$$

The column total is a measure of deviations from linearity and is approximately χ^2 distributed with degrees of freedom equal to $N - 2h$. Significance of this value may be assessed with the aid of Table 8.3 or a suitable sub-routine in a computer program. If the value is significant at the 0.05 probability level, the assay must probably be rejected (see Section 4.2.4).

When the above test gives no indication of significant deviations from linear regression, the deviations from parallelism are tested at the 0.05 significance level with:

$$\chi^2 = \sum \frac{S_{xy}^2}{S_{xx}} - \frac{(\sum S_{xy})^2}{\sum S_{xx}} \quad (4.2.2-2)$$

with $h - 1$ degrees of freedom.

4.2.3. ESTIMATION OF POTENCY AND CONFIDENCE LIMITS

When there are no indications for a significant departure from parallelism and linearity the $\ln(\text{potency ratio}) M'_T$ is calculated as:

$$M'_T = \frac{a_T - a_S}{b} \quad (4.2.3-1)$$

and the antilogarithm is taken. Now let $t = 1.96$ and $s = 1$. Confidence limits are calculated as the antilogarithms of:

$$CM'_T - (C-1)(\bar{x}_S - \bar{x}_T) \pm \sqrt{(C-1)\left(V \sum S_{xx} + C(M'_T - \bar{x}_S + \bar{x}_T)^2\right)} \quad (4.2.3-2)$$

$$\text{where } C = \frac{b^2 \sum S_{xx}}{b^2 \sum S_{xx} - s^2 t^2} \text{ and } V = \frac{1}{\sum w} + \frac{1}{\sum w}$$

Table 4.2.1-I. – First working table

4.2.4. INVALID ASSAYS

If the test for deviations from linearity described in Section 4.2.2 is significant, the assay should normally be rejected. If there are reasons to retain the assay, the formulae are slightly modified. t becomes the t -value ($p = 0.05$) with the same number of degrees of freedom as used in the check for linearity and s^2 becomes the χ^2 value divided by the same number of degrees of freedom (and thus typically is greater than 1).

The test for parallelism is also slightly modified. The χ^2 value for non-parallelism is divided by its number of degrees of freedom. The resulting value is divided by s^2 calculated above to obtain an F -ratio with $h - 1$ and $N - 2h$ degrees of freedom, which is evaluated in the usual way at the 0.05 significance level.

4.3. THE LOGIT METHOD

As indicated in Section 4.1 the logit method may sometimes be more appropriate. The name of the method is derived from the logit function which is the inverse of the logistic distribution. The procedure is similar to that described for the probit method with the following modifications in the formulae for Φ and Z .

$$\Phi = \frac{1}{1 + e^{-Y}} \quad (4.3.-1)$$

$$Z = \frac{e^{-Y}}{(1 + e^{-Y})^2} \quad (4.3.-2)$$

4.4. OTHER SHAPES OF THE CURVE

The probit and logit method are almost always adequate for the analysis of quantal responses called for in the European Pharmacopoeia. However, if it can be made evident that the $\ln(\text{dose})$ -response curve has another shape than the 2 curves described above, another curve Φ may be adopted. Z is then taken to be the first derivative of Φ .

For example, if it can be shown that the curve is not symmetric, the Gompertz distribution may be appropriate (the gompit method) in which case $\Phi = 1 - e^{-e^Y}$ and $Z = e^{Y-e^Y}$.

4.5. THE MEDIAN EFFECTIVE DOSE

In some types of assay it is desirable to determine a median effective dose which is the dose that produces a response in 50 per cent of the units. The probit method can be used to determine this median effective dose (ED_{50}), but since there is no need to express this dose relative to a standard, the formulae are slightly different.

Note: a standard can optionally be included in order to validate the assay. Usually the assay is considered valid if the calculated ED_{50} of the standard is close enough to the assigned ED_{50} . What "close enough" in this context means depends on the requirements specified in the monograph.

The tabulation of the responses to the test samples, and optionally a standard, is as described in Section 4.2.1. The test for linearity is as described in Section 4.2.2. A test for parallelism is not necessary for this type of assay. The ED_{50} of test sample T , and similarly for the other samples, is obtained as described in Section 4.2.3, with the following modifications in formulae 4.2.3.-1 and 4.2.3.-2).

$$M'_T = \frac{-a_T}{b} \quad (4.5.-1)$$

$$CM'_T - (C-1)\bar{x}_T \pm \sqrt{(C-1)\left(V \sum S_{xx} + C(M'_T + \bar{x}_T)^2\right)} \quad (4.5.-2)$$

$$\text{where } V = \frac{1}{\sum w} \text{ and } C \text{ is left unchanged}$$

5. EXAMPLES

This section consists of worked examples illustrating the application of the formulae. The examples have been selected primarily to illustrate the statistical method of calculation. They are not intended to reflect the most suitable method of assay, if alternatives are permitted in the individual monographs. To increase their value as program checks, more decimal places are given than would usually be necessary. It should also be noted that other, but equivalent methods of calculation exist. These methods should lead to exactly the same final results as those given in the examples.

5.1. PARALLEL-LINE MODEL

5.1.1. TWO-DOSE MULTIPLE ASSAY WITH COMPLETELY RANDOMISED DESIGN

An assay of corticotrophin by subcutaneous injection in rats

The standard preparation is administered at 0.25 and 1.0 unit per 100 g of body mass. 2 preparations to be examined are both assumed to have a potency of 1 unit per milligram and they are administered in the same quantities as the standard. The individual responses and means per treatment are given in Table 5.1.1.-I. A graphical presentation (Figure 5.1.1.I) gives no rise to doubt the homogeneity of variance and normality of the data, but suggests problems with parallelism for preparation U .

Table 5.1.1.-I. – Response metameter y - mass of ascorbic acid (mg) per 100 g of adrenal gland

	Standard S		Preparation T		Preparation U	
	S_1	S_2	T_1	T_2	U_1	U_2
	300	289	310	230	250	236
	310	221	290	210	268	213
	330	267	360	280	273	283
	290	236	341	261	240	269
	364	250	321	241	307	251
	328	231	370	290	270	294
	390	229	303	223	317	223
	360	269	334	254	312	250
	342	233	295	216	320	216
	306	259	315	235	265	265
Mean	332.0	248.4	323.9	244.0	282.2	250.0

Figure 5.1.1-I.

The formulae in Tables 3.2.3-I and 3.2.3-II lead to:

$$\begin{aligned} P_s &= 580.4 & L_s &= -41.8 \\ P_T &= 567.9 & L_T &= -39.95 \\ P_U &= 532.2 & L_U &= -16.1 \\ H_P &= \frac{10}{2} = 5 & H_L &= \frac{120}{6} = 20 \end{aligned}$$

The analysis of variance can now be completed with the formulae in Tables 3.2.3-III and 3.2.3-IV. This is shown in Table 5.1.1-II.

Table 5.1.1-II. – Analysis of variance

Source of variation	Degrees of freedom	Sum of squares	Mean square	F-ratio	Probability
Preparations	2	6256.6	3128.3		
Regression	1	63 830.8	63 830.8	83.38	0.000
Non-parallelism	2	8218.2	4109.1	5.37	0.007
Treatments	5	78 305.7			
Residual error	54	41 340.9	765.57		
Total	59	119 646.6			

The analysis confirms a highly significant linear regression. Departure from parallelism, however, is also significant ($p = 0.0075$) which was to be expected from the graphical observation that preparation *U* is not parallel to the standard. This preparation is therefore rejected and the analysis repeated using only preparation *T* and the standard.

Table 5.1.1-III. – Analysis of variance without sample *U*

Source of variation	Degrees of freedom	Sum of squares	Mean square	F-ratio	Probability
Preparations	1	390.6	390.6		
Regression	1	66 830.6	66 830.6	90.5	0.000
Non-parallelism	1	34.2	34.2	0.05	0.831
Treatments	3	67 255.5			
Residual error	36	26 587.3	738.54		
Total	39	93 842.8			

The analysis without preparation *U* results in compliance with the requirements with respect to both regression and parallelism and so the potency can be calculated. The formulae in Section 3.2.5 give:

– for the common slope:

$$b = \frac{20(-41.8 - 39.95)}{\ln 4 \times 10 \times 2} = -58.970$$

– the $\ln(\text{potency ratio})$ is:

$$\begin{aligned} M'_T &= \frac{567.9 - 580.4}{2 \times (-58.970)} = 0.1060 \\ C &= \frac{66\,830.6}{66\,830.6 - 738.54 \times 2.028^2} = 1.0476 \\ V &= \frac{66\,830.6}{(-58.970)^2 \times 2 \times 10} = 0.9609 \end{aligned}$$

– and $\ln(\text{confidence limits})$ are:

$$1.0476 \times 0.1060 \pm \sqrt{0.0476 \times (1.0476 \times 0.1060^2 + 2 \times 0.9609)} = 0.1110 \pm 0.3034$$

By taking the antilogarithms we find a potency ratio of 1.11 with 95 per cent confidence limits from 0.82-1.51.

Multiplying by the assumed potency of preparation *T* yields a potency of 1.11 units/mg with 95 per cent confidence limits from 0.82 to 1.51 units/mg.

5.1.2. THREE-DOSE LATIN SQUARE DESIGN

Antibiotic agar diffusion assay using a rectangular tray

The standard has an assigned potency of 4855 IU/mg. The test preparation has an assumed potency of 5600 IU/mg. For the stock solutions 25.2 mg of the standard is dissolved in 24.5 ml of solvent and 21.4 mg of the test preparation is dissolved in 23.95 ml of solvent. The final solutions are prepared by first diluting both stock solutions to 1/20 and further using a dilution ratio of 1.5.

A Latin square is generated with the method described in Section 8.6 (see Table 5.1.2-I). The responses of this routine assay are shown in Table 5.1.2-II (inhibition zones in mm $\times$ 10). The treatment mean values are shown in Table 5.1.2-III. A graphical representation of the data (see Figure 5.1.2-I) gives no rise to doubt the normality or homogeneity of variance of the data.

The formulae in Tables 3.2.3-I and 3.2.3-II lead to:

$$\begin{aligned} P_s &= 529.667 & L_s &= 35.833 \\ P_T &= 526.333 & L_T &= 39.333 \\ H_P &= \frac{6}{3} = 2 & H_L &= \frac{72}{24} = 3 \end{aligned}$$

The analysis of variance can now be completed with the formulae in Tables 3.2.3-III and 3.2.3-IV. The result is shown in Table 5.1.2-IV.

The analysis shows significant differences between the rows. This indicates the increased precision achieved by using a Latin square design rather than a completely randomised design. A highly significant regression and no significant departure of the individual regression lines from parallelism and linearity confirms that the assay is satisfactory for potency calculations.

Residual error	20	415.3333	20.7667		
Total	35	9556			

The formulae in Section 3.2.5 give:

– for the common slope:

$$b = \frac{3 \times (35.833 + 39.333)}{\ln(1.5) \times 6 \times 2} = 46.346$$

– the ln(potency ratio) is:

$$M'_T = \frac{526.333 - 529.667}{3 \times 46.346} = -0.023974$$

$$C' = \frac{8475.0417}{8475.0417 - 20.7667 \times 2.086^2} = 1.0108$$

$$V = \frac{8475.0417}{46.346^2 \times 3 \times 6} = 0.2192$$

– and ln(confidence limits) are:

$$\sqrt{\frac{1.0108 \times (-0.0240) \pm \sqrt{0.0108 \times (1.0108 \times (-0.0240)^2 + 2 \times 0.2192)}}{-0.02423 \pm 0.06878}}$$

The potency ratio is found by taking the antilogarithms, resulting in 0.9763 with 95 per cent confidence limits from 0.9112-1.0456.

A correction factor of $\frac{4855 \times 25.2/24.5}{5600 \times 21.4/23.95} = 0.99799$ is necessary because the dilutions were not exactly equipotent on the basis of the assumed potency. Multiplying by this correction factor and the assumed potency of 5600 IU/mg yields a potency of 5456 IU/mg with 95 per cent confidence limits from 5092 to 5843 IU/mg.

5.1.3. FOUR-DOSE RANDOMISED BLOCK DESIGN

Antibiotic turbidimetric assay

This assay is designed to assign a potency in international units per vial. The standard has an assigned potency of 670 IU/mg. The test preparation has an assumed potency of 20 000 IU/vial. On the basis of this information the stock solutions are prepared as follows. 16.7 mg of the standard is dissolved in 25 ml solvent and the contents of one vial of the test preparation are dissolved in 40 ml solvent. The final solutions are prepared by first diluting to 1/40 and further using a dilution ratio of 1.5. The tubes are placed in a water-bath in a randomised block arrangement (see Section 8.5). The responses are listed in Table 5.1.3-I.

Inspection of Figure 5.1.3-I gives no rise to doubt the validity of the assumptions of normality and homogeneity of variance of the data. The standard deviation of S_3 is somewhat high but is no reason for concern.

The formulae in Tables 3.2.3-I and 3.2.3-II lead to:

$$\begin{aligned} P_S &= 719.4 & L_S &= -229.1 \\ P_T &= 687.6 & L_T &= -222 \\ H_P &= \frac{5}{4} = 1.25 & H_L &= \frac{60}{60} = 1 \end{aligned}$$

The analysis of variance is constructed with the formulae in Tables 3.2.3-III and 3.2.3-IV. The result is shown in Table 5.1.3-II.

Table 5.1.3-I. – Absorbances of the suspensions ($\times 1000$)

Block	Standard S				Preparation T				Mean
	S ₁	S ₂	S ₃	S ₄	T ₁	T ₂	T ₃	T ₄	
1	252	207	168	113	242	206	146	115	181.1
2	249	201	187	107	236	197	153	102	179.0
3	247	193	162	111	246	197	148	104	176.0
4	250	207	155	108	231	191	159	106	175.9
5	235	207	140	98	232	186	146	95	167.4
Mean	246.6	203.0	162.4	107.4	237.4	195.4	150.4	104.4	

Figure 5.1.3-I.

Table 5.1.3-II. – Analysis of variance

Source of variation	Degrees of freedom	Sum of squares	Mean square	F-ratio	Probability
Preparations	1	632.025	632.025		
Regression	1	101 745.6	101 745.6	1887.1	0.000
Non-parallelism	1	25.205	25.205	0.467	0.500
Non-linearity	4	259.14	64.785	1.202	0.332
Treatments	7	102 662			
Blocks	4	876.75	219.188	4.065	0.010
Residual error	28	1509.65	53.916		
Total	39	105 048.4			

A significant difference is found between the blocks. This indicates the increased precision achieved by using a randomised block design. A highly significant regression

and no significant departure from parallelism and linearity confirms that the assay is satisfactory for potency calculations. The formulae in Section 3.2.5 give:

– for the common slope:

$$b = \frac{1 \times (-229.1 - 222)}{\ln(1.5) \times 5 \times 2} = -111.255$$

– the $\ln(\text{potency ratio})$ is:

$$\begin{aligned} M'_T &= \frac{687.6 - 719.4}{4 \times (-111.255)} = 0.071457 \\ C &= \frac{101\,745.6}{101\,745.6 - 53.916 \times 2.048^2} = 1.00223 \\ V &= \frac{101\,745.6}{(-111.255)^2 \times 4 \times 5} = 0.4110 \end{aligned}$$

– and $\ln(\text{confidence limits})$ are:

$$\begin{aligned} &1.00223 \times 0.0715 \pm \\ &\sqrt{0.00223 \times (1.00223 \times 0.0715^2 + 2 \times 0.4110)} \\ &= 0.07162 \pm 0.04293 \end{aligned}$$

The potency ratio is found by taking the antilogarithms, resulting in 1.0741 with 95 per cent confidence limits from 1.0291 to 1.1214. A correction factor of $\frac{670 \times 16.7/25}{20\,000 \times 1/40} = 0.89512$ is necessary because the dilutions were not exactly equipotent on the basis of the assumed potency. Multiplying by this correction factor and the assumed potency of 20 000 IU/vial yields a potency of 19 228 IU/vial with 95 per cent confidence limits from 18 423–20 075 IU/vial.

5.1.4. FIVE-DOSE MULTIPLE ASSAY WITH COMPLETELY RANDOMISED DESIGN

An *in-vitro* assay of three hepatitis B vaccines against a standard

3 independent two-fold dilution series of 5 dilutions were prepared from each of the vaccines. After some additional steps in the assay procedure, absorbances were measured. They are shown in Table 5.1.4-I.

Table 5.1.4-I. – Optical densities

Dilution	Standard S			Preparation T		
1:16 000	0.043	0.045	0.051	0.097	0.097	0.094
1:8000	0.093	0.099	0.082	0.167	0.157	0.178
1:4000	0.159	0.154	0.166	0.327	0.355	0.345
1:2000	0.283	0.295	0.362	0.501	0.665	0.576
1:1000	0.514	0.531	0.545	1.140	1.386	1.051

Dilution	Preparation U			Preparation V		
1:16 000	0.086	0.071	0.073	0.082	0.082	0.086
1:8000	0.127	0.146	0.133	0.145	0.144	0.173
1:4000	0.277	0.268	0.269	0.318	0.306	0.316
1:2000	0.586	0.489	0.546	0.552	0.551	0.624
1:1000	0.957	0.866	1.045	1.037	1.039	1.068

The logarithms of the optical densities are known to have a linear relationship with the logarithms of the doses. The mean responses of the $\ln$ -transformed optical densities are listed in Table 5.1.4-II. No unusual features are discovered in a graphical presentation of the data.

Table 5.1.4-II. – Means of the *ln*-transformed absorbances

S_1	-3.075	T_1	-2.344	U_1	-2.572	V_1	-2.485
S_2	-2.396	T_2	-1.789	U_2	-2.002	V_2	-1.874
S_3	-1.835	T_3	-1.073	U_3	-1.305	V_3	-1.161
S_4	-1.166	T_4	-0.550	U_4	-0.618	V_4	-0.554
S_5	-0.635	T_5	0.169	U_5	-0.048	V_5	0.047

Figure 5.1.4-I.

The formulae in Tables 3.2.3-I and 3.2.3-II give:

$$\begin{aligned}
 P_S &= -9.108 & L_S &= 6.109 \\
 P_T &= -5.586 & L_T &= 6.264 \\
 P_U &= -6.544 & L_U &= 6.431 \\
 P_V &= -6.027 & L_V &= 6.384 \\
 H_P &= \frac{3}{5} = 0.6 & H_L &= \frac{36}{120} = 0.3
 \end{aligned}$$

The analysis of variance is completed with the formulae in Tables 3.2.3-III and 3.2.3-IV. This is shown in Table 5.1.4-III.

Table 5.1.4-III. – Analysis of variance

Source of variation	Degrees of freedom	Sum of squares	Mean square	F-ratio	Probability
Preparations	3	4.475	1.492		
Regression	1	47.58	47.58	7126	0.000
Non-parallelism	3	0.0187	0.006	0.933	0.434
Non-linearity	12	0.0742	0.006	0.926	0.531
Treatments	19	52.152			
Residual error	40	0.267	0.0067		
Total	59	52.42			

A highly significant regression and a non-significant departure from parallelism and linearity confirm that the potencies can be safely calculated. The formulae in Section 3.2.5 give:

– for the common slope:

$$b = \frac{0.3 \times (6.109 + 6.264 + 6.431 + 6.384)}{\ln 2 \times 3 \times 4} = 0.90848$$

– the *ln*(potency ratio) for preparation *T* is:

$$M'_T = \frac{-5.586 - (-9.108)}{5 \times 0.90848} = 0.7752$$

$$C = \frac{47.58}{47.58 - 0.0067 \times 2.021^2} = 1.00057$$

$$V = \frac{47.58}{0.9085^2 \times 5 \times 3} = 3.8436$$

– and *ln*(confidence limits) for preparation *T* are:

$$\begin{aligned}
 &1.00057 \times 0.7752 \pm \\
 &\sqrt{0.00057 \times (1.00057 \times 0.7752^2 + 2 \times 3.8436)} \\
 &= 0.7756 \pm 0.0689
 \end{aligned}$$

By taking the antilogarithms a potency ratio of 2.171 is found with 95 per cent confidence limits from 2.027 to 2.327. All samples have an assigned potency of 20 µg protein/ml and so a potency of 43.4 µg protein/ml is found for test preparation *T* with 95 per cent confidence limits from 40.5–46.5 µg protein/ml.

The same procedure is followed to estimate the potency and confidence interval of the other test preparations. The results are listed in Table 5.1.4-IV.

Table 5.1.4-IV. – Final potency estimates and 95 per cent confidence intervals of the test vaccines (in µg protein/ml)

	Lower limit	Estimate	Upper limit
Vaccine <i>T</i>	40.5	43.4	46.5
Vaccine <i>U</i>	32.9	35.2	37.6
Vaccine <i>V</i>	36.8	39.4	42.2

5.1.5. TWIN CROSS-OVER DESIGN

Assay of insulin by subcutaneous injection in rabbits

The standard preparation was administered at 1 unit and 2 units per millilitre. Equivalent doses of the unknown preparation were used based on an assumed potency of 40 units per millilitre. The rabbits received subcutaneously 0.5 ml of the appropriate solutions according to the design in Table 5.1.5-I and responses obtained are shown in Table 5.1.5-II. The large variance illustrates the variation between rabbits and the need to employ a cross-over design.

Table 5.1.5-I. – Arrangements of treatments

	Group of rabbits			
	1	2	3	4
Day 1	S_1	S_2	T_1	T_2
Day 2	T_2	T_1	S_2	S_1

Table 5.1.5-II. – Response *y*: sum of blood glucose readings (mg/100 ml) at 1 hour and 2½ hours

	Group 1		Group 2		Group 3		Group 4	
	S_1	T_2	S_2	T_1	T_1	S_2	T_2	S_1
	112	104	65	72	105	91	118	144
	126	112	116	160	83	67	119	149

	101	68	55	100	91	68	31	71
Mean	95.6	82.8	69.6	93.3	89.9	66.6	72.4	106.8

Figure 5.1.5-I.

The analysis of variance is more complicated for this assay than for the other designs given because the component of the sum of squares due to parallelism is not independent of the component due to rabbit differences. Testing of the parallelism of the regression lines involves a second error-mean-square term obtained by subtracting the parallelism component and 2 “interaction” components from the component due to rabbit differences.

3 “interaction” components are present in the analysis of variance due to replication within each group:
days × preparation; days × regression; days × parallelism.

These terms indicate the tendency for the components (preparations, regression and parallelism) to vary from day to day. The corresponding *F*-ratios thus provide checks on these aspects of assay validity. If the values of *F* obtained are significantly high, care should be exercised in interpreting the results of the assay and, if possible, the assay should be repeated.

The analysis of variance is constructed by applying the formulae given in Tables 3.2.3-I to 3.2.3-III separately for both days and for the pooled set of data. The formulae in Tables 3.2.3-I and 3.2.3-II give:

Day 1:	$P_s = 165.25$	$L_s = -13$
	$P_T = 162.25$	$L_T = -8.75$
	$H_p = \frac{8}{2} = 4$	$H_L = \frac{96}{6} = 16$
Day 2:	$P_s = 173.38$	$L_s = -20.06$
	$P_T = 176.00$	$L_T = -5.25$
	$H_p = \frac{8}{2} = 4$	$H_L = \frac{96}{6} = 16$
Pooled:	$P_s = 169.31$	$L_s = -16.53$
	$P_T = 169.13$	$L_T = -7.00$
	$H_p = \frac{16}{2} = 8$	$H_L = \frac{192}{6} = 32$

and with the formulae in Table 3.2.3-III this leads to:

Day 1	Day 2	Pooled
$SS_{\text{prep}} = 18.000$	$SS_{\text{prep}} = 13.781$	$SS_{\text{prep}} = 0.141$
$SS_{\text{reg}} = 3784.5$	$SS_{\text{reg}} = 5125.8$	$SS_{\text{reg}} = 8859.5$
$SS_{\text{par}} = 144.5$	$SS_{\text{par}} = 1755.3$	$SS_{\text{par}} = 1453.5$

The interaction terms are found as Day 1 + Day 2 - Pooled.

$$SS_{\text{days} \times \text{prep}} = 31.64$$

$$SS_{\text{days} \times \text{reg}} = 50.77$$

$$SS_{\text{days} \times \text{par}} = 446.27$$

In addition the sum of squares due to day-to-day variation is calculated as:

$$SS_{\text{days}} = \frac{1}{2}N(D_1^2 + D_2^2) - K = 478.52$$

and the sum of squares due to blocks (the variation between rabbits) as:

$$SS_{\text{block}} = 2 \sum B_i^2 - K = 39\,794.7$$

where B_i is the mean response per rabbit.
The analysis of variance can now be completed as shown in Table 5.1.5-III.

Table 5.1.5-III. – Analysis of variance

Source of variation	Degrees of freedom	Sum of squares	Mean square	<i>F</i> -ratio	Probability
Non-parallelism	1	1453.5	1453.5	1.064	0.311
Days × Prep.	1	31.6	31.6	0.023	0.880
Days × Regr.	1	50.8	50.8	0.037	0.849
Residual error between rabbits	28	38\,258.8	1366.4		
Rabbits	31	39\,794.7	1283.7		
Preparations	1	0.14	0.14	0.001	0.975
Regression	1	8859.5	8859.5	64.532	0.000
Days	1	478.5	478.5	3.485	0.072
Days × non-par.	1	446.3	446.3	3.251	0.082
Residual error within rabbits	28	3844.1	137.3		
Total	63	53\,423.2			

The analysis of variance confirms that the data fulfil the necessary conditions for a satisfactory assay: a highly significant regression, no significant departures from parallelism, and none of the three interaction components is significant.

The formulae in Section 3.2.5 give:

– for the common slope:

$$b = \frac{32 \times (-16.53 - 7)}{\ln 2 \times 16 \times 2} = -33.95$$

– the ln(potency ratio) is:

$$M'_T = \frac{169.13 - 169.31}{2 \times (-33.95)} = 0.00276$$

$$C = \frac{8859.5}{8859.5 - 137.3 \times 2.048^2} = 1.0695$$

$$V = \frac{8859.5}{(-33.95)^2 \times 2 \times 16} = 0.2402$$

– and ln(confidence limits) are:

$$1.0695 \times 0.00276 \pm \sqrt{0.0695 \times (1.0695 \times 0.00276^2 + 2 \times 0.2402)} = 0.00295 \pm 0.18279$$

By taking the antilogarithms a potency ratio of 1.003 with 95 per cent confidence limits from 0.835 to 1.204 is found. Multiplying by $A_T = 40$ yields a potency of 40.1 units per millilitre with 95 per cent confidence limits from 33.4-48.2 units per millilitre.

5.2. SLOPE-RATIO MODEL

5.2.1. A COMPLETELY RANDOMISED (0,3,3)-DESIGN

An assay of factor VIII

A laboratory carries out a chromogenic assay of factor VIII activity in concentrates. The laboratory has no experience with the type of assay but is trying to make it operational. 3 equivalent dilutions are prepared of both the standard and the test preparation. In addition a blank is prepared, although a linear dose-response relationship is not expected for low doses. 8 replicates of each dilution are prepared, which is more than would be done in a routine assay.

A graphical presentation of the data shows clearly that the dose-response relationship is indeed not linear at low doses. The responses to blanks will therefore not be used in the calculations (further assays are of course needed to justify this decision). The formulae in Tables 3.3.3.1-I and 3.3.3.1-II yield.

$$\begin{aligned} P_S &= 0.6524 & P_T &= 0.5651 \\ L_S &= 1.4693 & L_T &= 1.2656 \\ a_S &= 0.318 & a_T &= 0.318 \\ b_S &= 0.329 & b_T &= 0.271 \\ G_S &= 0.1554 & G_T &= 0.1156 \\ J_S &= 4.17 \cdot 10^{-8} & J_T &= 2.84 \cdot 10^{-6} \end{aligned}$$

and

$$H_1 = 0.09524 \quad a' = 0.05298 \quad K = 1.9764$$

and the analysis of variance is completed with the formulae in Tables 3.3.3.1-III and 3.3.3.1-IV.

A highly significant regression and no significant deviations from linearity and intersection indicate that the potency can be calculated.

Slope of standard:

$$b'_S = \frac{6 \times 1.469 - 36 \times 0.0530}{84} = 0.0822$$

Slope of test sample:

$$b'_T = \frac{6 \times 1.266 - 36 \times 0.0530}{84} = 0.0677$$

Formula 3.3.5.1-3 gives:

$$R = \frac{0.0677}{0.0822} = 0.823$$

$$C = \frac{0.0822^2}{0.0822^2 - 3.86 \cdot 10^{-6} \times 2.018^2 \times 0.0357} = 1.000083$$

$$K' = 0.000083 \times 0.75 = 0.000062$$

and the 95 per cent confidence limits are:

$$0.823 \pm \sqrt{0.000083 \times 1.678 + 0.000062 \times (-1.646)} \\ = 0.823 \pm 0.006$$

The potency ratio is thus estimated as 0.823 with 95 per cent confidence limits from 0.817 to 0.829.

Table 5.2.1-I. – Absorbances

	Blank	Standard S (in IU/ml)			Preparation T (in IU/ml)

5.2.2. A COMPLETELY RANDOMISED (0,4,4,4)-DESIGN

An in-vitro assay of influenza vaccines

The haemagglutinin antigen (HA) content of 2 influenza vaccines is determined by single radial immunodiffusion. Both have a labelled potency of 15 µg HA per dose, which is equivalent with a content of 30 µg HA/ml. The standard has an assigned content of 39 µg HA/ml.

Standard and test vaccines are applied in 4 duplicate concentrations which are prepared on the basis of the assigned and the labelled contents. When the equilibrium

between the external and the internal reactant is established, the zone of the annulus precipitation area is measured. The results are shown in Table 5.2.2-I.

A graphical presentation of the data shows no unusual features. The formulae in Tables 3.3.3.1-I and 3.3.3.1-II yield

P_S	= 108.2	P_T	= 103.85	P_U	= 85.8
L_S	= 301.1	L_T	= 292.1	L_U	= 234.1
a_S	= 141.0	a_T	= 116.7	a_U	= 139.8
b_S	= 61.2	b_T	= 64.95	b_U	= 39.2
G_S	= 3114.3	G_T	= 2909.4	G_U	= 1917.3
J_S	= 0.223	J_T	= 2.227	J_U	= 0.083

and

H_I	= 0.0093	a'	= 11.04	K	= 14 785.8
-------	----------	------	---------	-----	------------

and the analysis of variance is completed with the formulae in Tables 3.3.3.1-III and 3.3.3.1-IV. This is shown in Table 5.2.2-II.

A highly significant regression and no significant deviations from linearity and intersection indicate that the potency can be calculated.

Slope of standard:

$$b'_S = \frac{6 \times 301.1 - 60 \times 11.04}{180} = 6.356$$

Slope of *T* is:

$$b'_T = \frac{6 \times 292.1 - 60 \times 11.04}{180} = 6.056$$

Slope of *U* is:

$$b'_U = \frac{6 \times 234.1 - 60 \times 11.04}{180} = 4.123$$

This leads to a potency ratio of $6.056/6.356 = 0.953$ for vaccine *T* and $4.123/6.356 = 0.649$ for vaccine *U*.

$$C = \frac{6.356^2}{6.356^2 - 1.068 \times 2.179^2 \times 0.0444} = 1.0056$$

$$K' = 0.0056 \times 0.625 = 0.0035$$

And the confidence limits are found with formula 3.3.5.1-4.

For vaccine *T*:

$$0.955 \pm \sqrt{0.0056 \times 1.913 + 0.0035 \times (-1.913)} = 0.955 \pm 0.063$$

For vaccine *U*:

$$0.649 \pm \sqrt{0.0056 \times 1.423 + 0.0035 \times (-1.301)} = 0.649 \pm 0.058$$

The HA content in µg/dose can be found by multiplying the potency ratios and confidence limits by the assumed content of 15 µg/dose. The results are given in Table 5.2.2-III.

Table 5.2.2-I. – Zone of precipitation area (mm²)

5.3. QUANTAL RESPONSES

5.3.1. PROBIT ANALYSIS OF A TEST PREPARATION AGAINST A REFERENCE

An in-vivo assay of a diphtheria vaccine

A diphtheria vaccine (assumed potency 140 IU/vial) is assayed against a standard (assigned potency 132 IU/vial). On the basis of this information, equivalent doses are prepared and randomly administered to groups of guinea-pigs. After a given period, the animals are challenged with diphtheria toxin and the number of surviving animals recorded as shown in Table 5.3.1-I.

Table 5.3.1-I. – Raw data from a diphtheria assay in guinea-pigs

Standard (S) Assigned potency 132 IU/vial			Test preparation (T) Assumed potency 140 IU/vial		
dose (IU/ml)	chal- lenged	protect- ed	dose (I.U./ml)	chal- lenged	protect- ed
1.0	12	0	1.0	11	0
1.6	12	3	1.6	12	4
2.5	12	6	2.5	11	8
4.0	11	10	4.0	11	10

The observations are transferred to the first working table and the subsequent columns are computed as described in Section 4.2.1. Table 5.3.1-II shows the first cycle of this procedure.

The sums of the last 6 columns are then calculated per preparation and transferred to the second working table (see Table 5.3.1-III). The results in the other columns are found with formulae 4.2.1-4 to 4.2.1-10. This yields a common slope b of 1.655.

The values for Y in the first working table are now replaced by $a + bx$ and a second cycle is carried out (see Table 5.3.1-IV).

The cycle is repeated until the difference between 2 consecutive cycles has become small. The second working table should then appear as shown in Table 5.3.1-V.

Linearity is tested as described in Section 4.2.2. The χ^2 -value with 4 degrees of freedom is $0.851 + 1.070 = 1.921$ representing a p -value of 0.750 which is not significant.

Since there are no significant deviations from linearity, the test for parallelism can be carried out as described in the same section. The χ^2 -value with 1 degree of freedom is

$$(16.71 + 17.27) - \frac{14.15^2}{5.89} = 0.001 \text{ representing a } p\text{-value of } 0.974 \text{ which is not significant.}$$

The $\ln(\text{potency ratio})$ can now be estimated as described in Section 4.2.3.

$$M'_T = \frac{-1.721 - (-2.050)}{2.401} = 0.137$$

Further:

$$C = \frac{2.401^2 \times 5.893}{2.401^2 \times 5.893 - 1^2 \times 1.960^2} = 1.127$$

$$V = \frac{1}{18.37} + \frac{1}{17.96} = 0.110$$

So $\ln$ confidence limits are:

$$0.155 - 0.013 \pm \sqrt{0.127(0.649 + 1.127 \times 0.036^2)} = 0.142 \pm 0.288$$

The potency and confidence limits can now be found by taking the antilogarithms and multiplying these by the assumed potency of 140 IU/vial. This yields an estimate of 160.6 IU/vial with 95 per cent confidence limits from 121.0-215.2 IU/vial.

5.3.2. LOGIT ANALYSIS AND OTHER TYPES OF ANALYSES OF A TEST PREPARATION AGAINST A REFERENCE

Results will be given for the situation where the logit method and other “classical” methods of this family are applied to the data in Section 5.3.1. This should be regarded as an exercise rather than an alternative to the probit method in this specific case. Another shape of the curve may be adopted only if this is supported by experimental or theoretical evidence.

Table 5.3.2-I. – Results by using alternative curves

	Logit	Gompit	Angle ^(*)
Φ	$\frac{1}{1 + e^{-Y}}$	$1 - e^{-e^Y}$	$\frac{1}{2} \sin Y + \frac{1}{2}$
Z	$\frac{e^{-Y}}{(1 + e^{-Y})^2}$	$e^{Y - e^Y}$	$\frac{1}{2} \cos Y$
slope b	4.101	2.590	1.717
χ^2 lin	2.15	3.56	1.50
χ^2 par	0.0066	0.168	0.0010
Potency	162.9	158.3	155.8
Lower limit	121.1	118.7	122.6
Upper limit	221.1	213.3	200.7

$$(*) \begin{cases} \text{If } Y < -\frac{1}{2}\pi \text{ then } \Phi = 0 \text{ and } Z = 0 \\ \text{If } Y > \frac{1}{2}\pi \text{ then } \Phi = 1 \text{ and } Z = 0 \end{cases}$$

5.3.3. THE ED_{50} DETERMINATION OF A SUBSTANCE USING THE PROBIT METHOD

An *in-vitro* assay of oral poliomyelitis vaccine

In an ED_{50} assay of oral poliomyelitis vaccine with 10 different dilutions in 8 replicates of 50 μ l on an ELISA-plate, results were obtained as shown in Table 5.3.3-I.

The observations are transferred to the first working table and the subsequent columns are computed as described in Section 4.2.1. Table 5.3.3-II shows the first cycle of this procedure.

Table 5.3.3-I. – Dilutions (10^x μ l of the undiluted vaccine)

-3.5	-4.0	-4.5	-5.0	-5.5	-6.0	-6.5	-7.0	-7.5	-8.0
+	+	+	+	-	-	-	-	-	-
+	+	+	+	-	-	-	-	-	-
+	+	-	-	-	-	-	-	-	-
+	+	+	+	-	-	-	-	-	-
+	+	+	-	-	-	-	-	-	-
+	+	+	+	+	-	-	-	-	-
+	+	+	+	+	-	+	-	-	-
+	+	+	+	-	+	-	-	-	-

The sums of the last 6 columns are calculated and transferred to the second working table (see Table 5.3.3-III). The results in the other columns are found with formulae 4.2.1-4 to 4.2.1-10. This yields a common slope b of -0.295 .

The values for Y in the first working table are now replaced by $a + bx$ and a second cycle is carried out. The cycle is repeated until the difference between 2 consecutive cycles has become small. The second working table should then appear as shown in Table 5.3.3-IV.

Linearity is tested as described in Section 4.2.2. The χ^2 -value with 8 degrees of freedom is 2.711 representing a p -value of 0.951 which is not significant.

The potency ratio can now be estimated as described in Section 4.5.

Figure 5.3.3-I.

$$M'_T = \frac{-(-7.931)}{-0.646} = -12.273$$

Further:

$$C = \frac{(-0.646)^2 \times 55.883}{(-0.646)^2 \times 55.883 - 1^2 \times 1.960^2} = 1.197$$

$$V = \frac{1}{19.39} = 0.052$$

So ln confidence limits are:

$$\begin{aligned} & -14.692 - (-2.420) \pm \sqrt{0.197 \times (2.882 + 1.197 \times 0.009^2)} \\ & = -12.272 \pm 0.754 \end{aligned}$$

This estimate is still expressed in terms of the ln(dilutions). In order to obtain estimates expressed in ln(ED_{50})/ml the values are transformed to $-M'_T + \ln\left(\frac{1000}{50}\right)$.

Since it has become common use to express the potency of this type of vaccine in terms of $\log_{10}(\text{ED}_{50})/\text{ml}$, the results have to be divided by $\ln(10)$. The potency is thus estimated as $6.63 \log_{10}(\text{ED}_{50})/\text{ml}$ with 95 per cent confidence limits from 6.30 to $6.96 \log_{10}(\text{ED}_{50})/\text{ml}$.

5.4. EXTENDED SIGMOID DOSE-RESPONSE CURVES

5.4.1. FOUR-PARAMETER LOGISTIC CURVE ANALYSIS

A serological assay of tetanus sera

As already stated in Section 3.4, this example is intended to illustrate a “possible” way to analyse the data presented, but not necessarily to reflect the “only” or the “most appropriate” way. Many other approaches can be found in the literature, but in most cases they should not yield dramatically different outcomes. A short discussion of alternative approaches and other statistical considerations is given in Section 7.5.

A guinea-pig antiserum is assayed against a standard serum (0.4 IU/ml) using an enzyme-linked immunosorbent assay technique (ELISA). 10 two-fold dilutions of each serum were applied on a 96-well ELISA plate. Each dilution was applied twice. The observed responses are listed in Table 5.4.1.-I.

For this example, it will be assumed that the laboratory has validated conditions 1 to 3 in Section 3.1.1 when the assay was being developed for routine use. In addition, the laboratory has validated that the upper limit and lower limit of the samples can be assumed to be equal.

No unusual features are discovered in a graphical representation. A least squares method of a suitable computer program is used to fit the parameters of the logistic function, assuming that the residual error terms are independent and identically distributed normal random variables. In this case, 3 parameters (α , β and δ) are needed to describe the common slope-factor and the common lower and upper asymptotes. 2 additional parameters (γ_s and γ_T) are needed to describe the horizontal location of the 2 curves.

The following estimates of the parameters are returned by the program:

$$\begin{aligned}\alpha &= 3.196 & \gamma_s &= -4.307 \\ \beta &= 1.125 & \gamma_T &= -4.684 \\ \delta &= 0.145\end{aligned}$$

In addition, the estimated residual variance (s^2) is returned as 0.001429 with 20 degrees of freedom (within-treatments variation).

In order to obtain confidence limits, and also to check for parallelism and linearity, the observed responses (u) are linearised and submitted to a weighted parallel-line analysis by the program. This procedure is very similar to that described in Section 4.2 for probit analysis with the following modifications:

$$\begin{aligned}Y &= \beta(x - \gamma) & y &= Y + \frac{\left(\frac{u - \delta}{\alpha - \delta}\right) - \Phi}{Z} \\ \Phi &= \frac{1}{1 + e^{-Y}} & w &= \frac{Z^2(\alpha - \delta)^2}{s^2} \\ Z &= \frac{e^{-Y}}{(1 + e^{-Y})^2}\end{aligned}$$

The resulting weighted analysis of variance of the transformed responses (y) using weights (w) is as follows:

There are no significant deviations from parallelism and linearity and thus the assay is satisfactory for potency calculations. If the condition of equal upper and lower asymptotes is not fulfilled, significant deviations from linearity and/or parallelism are likely to occur because the tests for linearity and parallelism reflect the goodness of fit of the complete four-parameter model. The residual error in the analysis of variance is always equal to 1 as a result of the transformation. However, a heterogeneity factor (analogous to that for the probit model) can be computed.

The relative potency of the test preparation can be obtained as the antilogarithm of $\gamma_s - \gamma_r$. Multiplying by the assigned potency of the standard yields an estimate of $1.459 \times 0.4 = 0.584$ IU/ml. Formula 4.2.3.-2 gives 95 per cent confidence limits from 0.557-0.612 IU/ml.

6. COMBINATION OF ASSAY RESULTS

6.1. INTRODUCTION

Replication of independent assays and combination of their results is often needed to fulfil the requirements of the European Pharmacopoeia. The question then arises as to whether it is appropriate to combine the results of such assays and if so in what way.

2 assays may be regarded as mutually independent when the execution of either does not affect the probabilities of the possible outcomes of the other. This implies that the random errors in all essential factors influencing the result (for example, dilutions of the standard and of the preparation to be examined, the sensitivity of the biological indicator) in one assay must be independent of the corresponding random errors in the other one. Assays on successive days using the original and retained dilutions of the standard therefore are not independent assays.

There are several methods for combining the results of independent assays, the most theoretically acceptable being the most difficult to apply. 3 simple, approximate methods are described below; others may be used provided the necessary conditions are fulfilled.

Before potencies from assays based on the parallel-line or probit model are combined they must be expressed in logarithms; potencies derived from assays based on the

slope-ratio model are used as such. As the former models are more common than those based on the slope-ratio model, the symbol M denoting $\ln$ potency is used in the formulae in this section; by reading R (slope-ratio) for M , the analyst may use the same formulae for potencies derived from assays based on the slope-ratio model. All estimates of potency must be corrected for the potency assigned to each preparation to be examined before they are combined.

6.2. WEIGHTED COMBINATION OF ASSAY RESULTS

This method can be used provided the following conditions are fulfilled:

- 1) the potency estimates are derived from independent assays;
- 2) for each assay C is close to 1 (say less than 1.1);
- 3) the number of degrees of freedom of the individual residual errors is not smaller than 6, but preferably larger than 15;
- 4) the individual potency estimates form a homogeneous set (see Section 6.2.2).

When these conditions are not fulfilled this method cannot be applied. The method described in Section 6.3 may then be used to obtain the best estimate of the mean potency to be adopted in further assays as an assumed potency.

6.2.1. CALCULATION OF WEIGHTING COEFFICIENTS

It is assumed that the results of each of the n' assays have been analysed to give n' values of M with associated confidence limits. For each assay the logarithmic confidence interval L is obtained by subtracting the lower limit from the upper. A weight W for each value of M is calculated from equation 6.2.1.-1, where t has the same value as that used in the calculation of confidence limits.

$$W = \frac{4t^2}{L^2} \quad (6.2.1.-1)$$

6.2.2. HOMOGENEITY OF POTENCY ESTIMATES

By squaring the deviation of each value of M from the weighted mean, multiplying by the appropriate weight and summing over all assays, a statistic is obtained which is approximately distributed as χ^2 (see Table 8.3) and which may be used to test the homogeneity of a set of $\ln$ potency estimates:

$$\chi^2 \approx \sum_{n'} W (M - \bar{M})^2 \quad \text{where} \quad \bar{M} = \frac{\sum WM}{\sum W} \quad (6.2.2.-1)$$

If the calculated χ^2 is smaller than the tabulated value corresponding to $(n' - 1)$ degrees of freedom the potencies are homogeneous and the mean potency and limits obtained in Section 6.2.3 will be meaningful.

If the calculated value of this statistic is greater than the tabulated value, the potencies are heterogeneous. This means that the variation between individual estimates of M is greater than would have been predicted from the estimates of the confidence limits, i.e. that there is a significant variability between the assays. Under these circumstances condition 4 is not fulfilled and the equations in Section 6.2.3 are no longer applicable. Instead, the formulae in Section 6.2.4 may be used.

6.2.3. CALCULATION OF THE WEIGHTED MEAN AND CONFIDENCE LIMITS

The products WM are formed for each assay and their sum divided by the total weight for all assays to give the logarithm of the weighted mean potency.

$$\bar{M} = \frac{\sum WM}{\sum W} \quad (6.2.3.-1)$$

The standard error of the $\ln$ (mean potency) is taken to be the square root of the reciprocal of the total weight:

$$s_{\overline{M}} = \sqrt{\frac{1}{\sum W}} \quad (6.2.3-2)$$

and approximate confidence limits are obtained from the antilogarithms of the value given by

$$\overline{M} \pm t \times s_{\overline{M}} \quad (6.2.3-3)$$

where the number of degrees of freedom of t equals the sum of the number of degrees of freedom for the error mean squares in the individual assays.

6.2.4. WEIGHTED MEAN AND CONFIDENCE LIMITS BASED ON THE INTRA- AND INTER-ASSAY VARIATION

When results of several repeated assays are combined, the (χ^2 -value may be significant. The observed variation is then considered to have two components:

- the intra-assay variation $s_M^2 = 1/W$,
- the inter-assay variation $s_{\overline{M}}^2 = \frac{\sum (M - \overline{M})^2}{n'(n' - 1)}$

where $\overline{M}$ is the unweighted mean. The former varies from assay to assay whereas the latter is common to all M .

For each M a weighting coefficient is then calculated as:

$$W' = \frac{1}{s_M^2 + s_{\overline{M}}^2}$$

which replaces W in Section 6.2.3. where t is taken to be approximately 2.

6.3. UNWEIGHTED COMBINATION OF ASSAY RESULTS

To combine the n' estimates of M from n' assays in the simplest way, the mean is calculated and an estimate of its standard deviation is obtained by calculating:

$$s_{\overline{M}}^2 = \frac{\sum (M - \overline{M})^2}{n'(n' - 1)} \quad (6.3-1)$$

and the limits are:

$$\overline{M} \pm ts_{\overline{M}} \quad (6.3-2)$$

where t has $(n' - 1)$ degrees of freedom. The number n' of estimates of M is usually small, and hence the value of t is quite large.

6.4. EXAMPLE OF A WEIGHTED MEAN POTENCY WITH CONFIDENCE LIMITS

Table 6.4-I lists 6 independent potency estimates of the same preparation together with their 95 per cent confidence limits and the number of degrees of freedom of their error variances. Conditions 1, 2 and 3 in Section 6.2. are met. The $\ln$ potencies and the weights are calculated as described in Section 6.2.

Table 6.4-I. – Potency estimates and confidence intervals of 6 independent assays

Potency estimate (I.U./vial)	Lower limit (I.U./vial)	Upper limit (I.U./vial)	Degrees of freedom	$\ln$ potency M	Weight W
18 367	17 755	19 002	20	9.8183	3777.7
18 003	17 415	18 610	20	9.7983	3951.5
18 064	17 319	18 838	20	9.8017	2462.5
17 832	17 253	18 429	20	9.7887	4003.0
18 635	17 959	19 339	20	9.8328	3175.6
18 269	17 722	18 834	20	9.8130	4699.5

Homogeneity of potency estimates is assessed with formula 6.2.2-1 which gives a χ^2 of 4.42 with 5 degrees of freedom. This is not significant ($p = 0.49$) and thus all conditions are met.

A weighted mean potency is calculated with formula 6.2.3-1 which yields 9.8085.

Formula 6.2.3-2 gives a standard deviation of 0.00673 and approximate 95 per cent confidence limits of 9.7951 and 9.8218 are calculated with formula 6.2.3-3 where t has 120 degrees of freedom.

By taking the antilogarithms a potency of 18 187 IU/vial is found with 95 per cent confidence limits from 17 946-18 431 IU/vial.

7. BEYOND THIS ANNEX

It is impossible to give a comprehensive treatise of statistical methods in a pharmacopoeial text. However, the methods described in this annex should suffice for most pharmacopoeial purposes. This section tries to give a more abstract survey of alternative or more general methods that have been developed. The interested reader is encouraged to further explore the existing literature in this area. The use of more specialised statistical methods should, in any case, be left to qualified personnel.

7.1. GENERAL LINEAR MODELS

The methods given in this annex can be described in terms of general linear models (or generalised linear models to include the probit and logit methods). The principle is to define a linear structure matrix X (or design matrix) in which each row represents an observation and each column a linear effect (preparation, block, column, dose). For example: the Latin square design in example 5.1.2 would involve a matrix with 36 rows and 13 columns. 1 column for each of the preparations, 1 column for the doses, 5 columns for each block except the first, and 5 columns for each row except the first. All columns, except the one for doses, are filled with 0 or 1 depending on whether or not the observation relates to the effect. A vector Y is filled with the (transformed) observations. The effects are estimated with the formula $(X'X)^{-1}X'Y$ from which the potency estimate m can easily be derived as a ratio of relevant effects. Confidence intervals are calculated from Fieller's theorem:

$$m_l, m_u = \frac{\left[m - \frac{g v_{12}}{v_{22}} \pm \frac{t_s}{b} \sqrt{v_{11} - 2m v_{12} + m^2 v_{22} - g \left(v_{11} - \frac{v_{12}^2}{v_{22}} \right)} \right]}{(1 - g)}$$

where $g = \frac{t^2 s^2 v_{22}}{b^2}$

and v_{11} , v_{22} , v_{12} represent the variance multipliers for the numerator, the denominator and their covariance multiplier respectively. These are taken directly from $(X'X)^{-1}$ or indirectly by noting that:

$$\text{Var}(a_1 - a_2) = \text{Var}(a_1) + \text{Var}(a_2) - 2\text{Cov}(a_1, a_2)$$

$$\text{and } \text{Cov}(a_1 - a_2, b) = \text{Cov}(a_1, b) - \text{Cov}(a_2, b)$$

A full analysis of variance in which all components are partitioned is slightly more complicated as it involves a renewed definition of X with more columns to relax the assumptions of parallelism and linearity, after which the linear hypotheses can be tested. For assays depending upon quantal responses the linear effects (intercepts a_s , a_T etc. and the common slope b are found by maximising the sum over treatments of $n \ln \Phi(a_i + bx) + (n - r) \ln(1 - \Phi(a_i + bx))$ where x is the $\ln(\text{dose})$, Φ denotes the shape of the distribution and $i \in \{S, T, \dots\}$.

7.2. HETEROGENEITY OF VARIANCE

Heterogeneity of variance cannot always be solved by simply transforming the responses. A possible way to cope with this problem is to perform a weighted linear regression. In order to obtain an unbiased estimate, the weight of the observations is taken to be proportional to the reciprocal of the error variances. Since the true error variance is not always known, an iterative reweighted linear procedure may be followed. However, the calculation of the confidence interval involves new problems.

7.3. OUTLIERS AND ROBUST METHODS

The method of least squares described in this annex has the disadvantage of being very sensitive to outliers. A clear outlier may completely corrupt the calculations. This problem is often remedied by discarding the outlying result from the dataset. This policy can lead to arbitrary rejection of data and is not always without danger. It is not easy to give a general guideline on how to decide whether or not a specific observation is an outlier and it is for this reason that many robust methods have been developed. These methods are less sensitive to outliers because they give less weight to observations that are far away from the predicted value. New problems usually arise in computing confidence intervals or defining a satisfactory function to be minimised.

7.4. CORRELATED ERRORS

Absolute randomisation is not always feasible or very undesirable from a practical point of view. Thus, subsequent doses within a dilution series often exhibit correlated errors leading to confidence limits that are far too narrow. Some methods have been developed that take account of this autocorrelation effect.

7.5. EXTENDED NON-LINEAR DOSE-RESPONSE CURVES

Analysis of extended non-linear dose-response curves raises a number of statistical questions which require consideration, and for which professional advice is recommended. Some of these are indicated below.

- 1) An example using the four-parameter logistic function has been shown. However, models based on functions giving other sigmoid curves may also be used. Models incorporating additional asymmetry parameters have been suggested.
- 2) Heterogeneity of variance is common when responses cover a wide range. If the analysis ignores the heterogeneity, interpretation of results may not be correct and estimates may be biased. Use of the reciprocal of the error variances as weights is unlikely to be reliable with limited numbers of replicates. It may be appropriate to estimate a function which relates variance to mean response.
- 3) The statistical curve-fitting procedures may give different estimates depending on assumptions made about the homogeneity of the variance and on the range of responses used.
- 4) In principle, equality of upper and lower response limits for the different preparations included in an assay can be directly tested in each assay. However, interpretation of the results of these tests may not be straightforward. The tests for linearity and parallelism given by the simplified method of analysis (Example 5.4.1) indirectly incorporate tests for equality and accuracy of upper and lower limits.
- 5) Many assays include "controls" which are intended to identify the upper and/or lower response limits. However, these values may not be consistent with the statistically fitted upper and lower response limits based on the extended dose-response curve.
- 6) The simplified method of analysis given in Example 5.4.1 provides approximate confidence intervals. Other methods may also be used, for example intervals based on lack-of-fit of the completely specified model. For typical assay data, with responses covering the complete range for each preparation tested, all methods give similar results.

8. TABLES AND GENERATING PROCEDURES

The tables in this section list the critical values for the most frequently occurring numbers of degrees of freedom. If a critical value is not listed, reference should be made to more extensive tables. Many computer programs include statistical functions and their use is recommended instead of the tables in this section. Alternatively, the generating procedures given below each table can be used to compute the probability corresponding to a given statistic and number of degrees of freedom.

8.1. THE *F*-DISTRIBUTION

If an observed value is higher than the value in Table 8.1-I, it is considered to be significant (upper lines, $p = 0.05$) and highly significant (lower lines, $p = 0.01$). $df1$ is the number of degrees of freedom of the numerator and $df2$ is the number of degrees of freedom of the denominator.

Generating procedure. Let F be the F -ratio and $df1$ and $df2$ as described above. Let $\pi = 3.14159265358979...$ The procedure in Table 8.1-II will then generate the p -value.

8.2. THE *t*-DISTRIBUTION

If an observed value is higher than the value in Table 8.2-I, it is considered to be significant ($p = 0.05$) and highly significant ($p = 0.01$).

Generating procedures. The p -value for a given t with df degrees of freedom can be found with the procedures in Section 8.1 where $F = t^2$, $df1 = 1$ and $df2 = df$.

The t -value ($p = 0.05$) for a given number of degrees of freedom df can be found with the procedure in Table 8.2-II which should be accurate up to 6 decimal places.

Table 8.1-I – Critical values of the *F*-distribution

0.75	0.773	1.75	0.960	2.75	0.997
0.80	0.788	1.80	0.964	2.80	0.997
0.85	0.802	1.85	0.968	2.85	0.998
0.90	0.816	1.90	0.971	2.90	0.998
0.95	0.829	1.95	0.974	2.95	0.998

The Φ -value for negative x is found from table 8.4-I as $1 - \Phi(-x)$.

Generating procedure: Let x be the x -value. The procedure in Table 8.4-II will generate the corresponding Φ -value if $0 \leq x \leq 8.15$. If x is greater than 8.15 the Φ -value can be set to 1. If x is negative, the formula given above can be used.

This procedure assumes that the computer can represent about 15 decimal places. If less digits or more digits can be represented, the procedure needs some trivial modifications.

Table 8.4-II – *Generating procedure for the Φ -distribution*

s=0
t=x
i=1
repeat
s=s+t
i=i+2
t=t*x*x/i
until t<1E-16
phi=0.5+s*exp(-x*x/2)/sqr(2*pi)

8.5. RANDOM PERMUTATIONS

Random permutations are needed in randomised block designs. The following algorithm shows how the built-in random generator of a computer can be used to create random permutations of N treatments.

Step 1. Write the N possible treatments down in a row.

Step 2. Obtain a random integer r such that $1 \leq r \leq N$.

Step 3. Exchange the r -th treatment with the N -th treatment in the row.

Step 4. Let $N = N - 1$ and repeat steps 2 to 4 until $N = 1$.

An example with 6 treatments will illustrate this algorithm.

1.	$N = 6$	S_1	S_2	S_3	T_1	T_2	T_3
2.	$r = 2$		→				←
3.		S_1	T_3	S_3	T_1	T_2	S_2
4.	$N = 5$						
2.	$r = 4$				→		←
3.		S_1	T_3	S_3	T_2	T_1	S_2
4.	$N = 4$						
2.	$r = 4$				↓		
3.		S_1	T_3	S_3	T_2	T_1	S_2
4.	$N = 3$						
2.	$r = 1$	→			←		
3.		S_3	T_3	S_1	T_2	T_1	S_2
4.	$N = 2$						
2.	$r = 1$	→		←			
3.		T_3	S_3	S_1	T_2	T_1	S_2
4.	$N = 1$						

8.6. LATIN SQUARES

The following example shows how 3 independent permutations can be used to obtain a Latin square.

1). Generate a random permutation of the N possible treatments (see Section 8.5):

T_3	S_3	S_1	T_2	T_1	S_2
-------	-------	-------	-------	-------	-------

2). A simple Latin square can now be constructed by “rotating” this permutation to the right. This can be done as follows. Write the permutation found in step 1 down on the first row. The second row consists of the same permutation, but with all treatments shifted to the right. The rightmost

treatment is put on the empty place at the left. This is repeated for all the rows until all the treatments appear once in each column:

T_3	S_3	S_1	T_2	T_1	S_2
S_2	T_3	S_3	S_1	T_2	T_1
T_1	S_2	T_3	S_3	S_1	T_2
T_2	T_1	S_2	T_3	S_3	S_1
S_1	T_2	T_1	S_2	T_3	S_3
S_3	S_1	T_2	T_1	S_2	T_3

3). Generate 2 independent random permutations of the figures 1 to N :

– one for the rows:

2	3	6	1	4	5
---	---	---	---	---	---

– and one for the columns:

3	4	6	2	5	1
---	---	---	---	---	---

4). The Latin square can now be found by sorting the rows and columns of the simple Latin square according to the 2 permutations for the rows and columns:

	3	4	6	2	5	1
2	T_3	S_3	S_1	T_2	T_1	S_2
3	S_2	T_3	S_3	S_1	T_2	T_1
6	T_1	S_2	T_3	S_3	S_1	T_2
1	T_2	T_1	S_2	T_3	S_3	S_1
4	S_1	T_2	T_1	S_2	T_3	S_3
5	S_3	S_1	T_2	T_1	S_2	T_3
	↓					
	1	2	3	4	5	6
1	S_1	T_3	T_2	T_1	S_3	S_2
2	S_2	T_2	T_3	S_3	T_1	S_1
3	T_1	S_1	S_2	T_3	T_2	S_3
4	S_3	S_2	S_1	T_2	T_3	T_1
5	T_3	T_1	S_3	S_1	S_2	T_2
6	T_2	S_3	T_1	S_2	S_1	T_3

9. GLOSSARY OF SYMBOLS

Symbol	Definition
a	Intersection of linear regression of responses on dose or $\ln(\text{dose})$
b	Slope of linear regression of responses on dose or on $\ln(\text{dose})$
d	Number of dose levels for each preparation (excluding the blank in slope-ratio assays)
e	Base of natural logarithms (= 2.71828182845905...)

Symbol	Definition
g	Statistic used in Fieller's theorem: $g = \frac{C - 1}{C}$
h	Number of preparations in an assay, including the standard preparation
m	Potency estimate obtained as a ratio of effects in general linear models
n	Number of replicates for each treatment
p	Probability of a given statistic being larger than the observed value. Also used as the ratio r/n in probit analysis
r	The number of responding units per treatment group in assays depending upon quantal responses
s	Estimate of standard deviation (= $\sqrt{s^2}$)
s^2	Estimate of residual variance given by error mean square in analysis of variance
t	Student's statistic (Table 8.2.)
u	Observed response in four-parameter analysis
v_{11}, v_{12}, v_{22}	(Co)variance multipliers for numerator and denominator of ratio m in Fieller's theorem
w	Weighting coefficient
x	The $\ln(\text{dose})$
y	Individual response or transformed response
A	Assumed potencies of test preparations when making up doses
B	Mean response to blanks in slope-ratio assays
C	Statistic used in the calculation of confidence intervals: $C = \frac{1}{1 - g}$
$C_p \dots, C_n$	Mean response to each column of a Latin square design
D_1, D_2	Mean response on time 1 or time 2 in the twin cross-over design
F	Ratio of 2 independent estimates of variance following an F -distribution (Table 8.1.)
$G_S, G_P \dots$	Treatment values used in the analysis of variance for slope-ratio assays
H_P, H_L	Multipliers used in the analysis of variance for parallel-line assays
H_P, H_I	Multipliers used in the analysis of variance for slope-ratio assays

Symbol	Definition	Symbol	Definition
I	In parallel-line assays, the ln of the ratio between adjacent doses. In slope-ratio assays, the interval between adjacent doses	Y	Vector representing the (transformed) responses in general linear models
$J_S, J_P, \dots$	Linearity values used in the analysis of variance for slope-ratio assays	Z	The first derivative of Φ
K	Correction term used in the calculation of sums of squares in the analysis of variance	α	Upper asymptote of the ln(dose)-response curve in four-parameter analysis
L	Width of confidence interval in logarithms	β	Slope-factor of the ln(dose)-response curve in four-parameter analysis
$L_S, L_P, \dots$	Linear contrasts of standard and test preparations	γ	The ln(dose) giving 50 per cent response in the four-parameter analysis
M'	ln potency ratio of a given test preparation	δ	Lower asymptote of the ln(dose)-response curve in four-parameter analysis
N	Total number of treatments in the assay (= dh)	π	3.141592653589793238...
$P_S, P_P, \dots$	Sum of standard and test preparations	Φ	Cumulative standard normal distribution function (Table 8.4.)
R	Estimated potency of a given test preparation	χ^2	Chi-square statistic (Table 8.3.)
R'	Potency ratio of a given test preparation	10. LITERATURE <i>This section lists some recommended literature for further study.</i> Finney, D.J. (1971). <i>Probit Analysis</i> , 3 rd Ed. 5.4. RESIDUAL SOLVENTS

LIMITING RESIDUAL SOLVENT LEVELS IN ACTIVE SUBSTANCES, EXCIPIENTS AND MEDICINAL PRODUCTS

The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH) has adopted Impurities Guidelines for Residual Solvents which prescribes limits for the content of solvents which may remain in active substances, excipients and medicinal products after processing. This guideline, the text of which is reproduced below, excludes existing marketed products. The European Pharmacopoeia is, however, applying the same principles enshrined in the guideline to existing active substances, excipients and medicinal products whether or not they are the subject of a monograph of the Pharmacopoeia. All substances and products are to be tested for the content of solvents likely to be present in a substance or product.

Where the limits to be applied comply with those given below, tests for residual solvents are not generally mentioned in specific monographs since the solvents employed may vary from one manufacturer to another and the requirements of this general chapter are applied via the general monograph on *Substances for Pharmaceutical Use (2034)*. The competent authority is to be informed of the solvents employed during the production process. This information is also given in the dossier submitted for a certificate of suitability of the monographs of the European Pharmacopoeia and is mentioned on the certificate.

Where only Class 3 solvents are used, a test for loss on drying may be applied or a specific determination of the solvent may be made. If for a Class 3 solvent a justified and authorised limit higher than 0.5 per cent is applied, a specific determination of the solvent is required.

When Class 1 residual solvents or Class 2 residual solvents (or Class 3 residual solvents which exceed the 0.5 per cent) are used, the methodology described in the general method (2.4.24) is to be applied wherever possible. Otherwise an appropriate validated method is to be employed.

When a quantitative determination of a residual solvent is carried out, the result is taken into account for the calculation of the content of the substance except where a test for drying is carried out.

APPENDIX 1. LIST OF SOLVENTS INCLUDED IN THE GUIDELINE

APPENDIX 2. ADDITIONAL BACKGROUND

A2.1: ENVIRONMENTAL REGULATION OF ORGANIC VOLATILE SOLVENTS

A2.2: RESIDUAL SOLVENTS IN PHARMACEUTICALS

APPENDIX 3. METHODS FOR ESTABLISHING EXPOSURE LIMITS

1. INTRODUCTION

The objective of this guideline is to recommend acceptable amounts of residual solvents in pharmaceuticals for the safety of the patient. The guideline recommends the use of less toxic solvents and describes levels considered to be toxicologically acceptable for some residual solvents.

Residual solvents in pharmaceuticals are defined here as organic volatile chemicals that are used or produced in the manufacture of active substances or excipients, or in the preparation of medicinal products. The solvents are not completely removed by practical manufacturing techniques. Appropriate selection of the solvent for the synthesis of active substance may enhance the yield, or determine characteristics such as crystal form, purity, and solubility. Therefore, the solvent may sometimes be a critical parameter in the synthetic process. This guideline does not address solvents deliberately used as excipients nor does it address solvates. However, the content of solvents in such products should be evaluated and justified.

Since there is no therapeutic benefit from residual solvents, all residual solvents should be removed to the extent possible to meet product specifications, good manufacturing practices, or other quality-based requirements. Medicinal products should contain no higher levels of residual solvents than can be supported by safety data. Some solvents that are known to cause unacceptable toxicities (Class 1, Table 1) should be avoided in the production of active substances, excipients, or medicinal products unless their use can be strongly justified in a risk-benefit assessment. Some solvents associated with less severe toxicity (Class 2, Table 2) should be limited in order to protect patients from potential adverse effects. Ideally, less toxic solvents (Class 3, Table 3) should be used where practical. The complete list of solvents included in this guideline is given in Appendix 1.

The lists are not exhaustive and other solvents can be used and later added to the lists. Recommended limits of Class 1 and 2 solvents or classification of solvents may change as new safety data becomes available. Supporting safety data in a marketing application for a new medicinal product containing a new solvent may be based on concepts in this guideline or the concept of qualification of impurities as expressed in the guideline for active substances (Q3A,

Impurities in New Active Substances) or medicinal products (Q3B, Impurities in New Medicinal Products), or all three guidelines.

2. SCOPE OF THE GUIDELINE

Residual solvents in active substances, excipients, and in medicinal products are within the scope of this guideline. Therefore, testing should be performed for residual solvents when production or purification processes are known to result in the presence of such solvents. It is only necessary to test for solvents that are used or produced in the manufacture or purification of active substances, excipients, or medicinal product. Although manufacturers may choose to test the medicinal product, a cumulative method may be used to calculate the residual solvent levels in the medicinal product from the levels in the ingredients used to produce the medicinal product. If the calculation results in a level equal to or below that recommended in this guideline, no testing of the medicinal product for residual solvents need be considered. If however, the calculated level is above the recommended level, the medicinal product should be tested to ascertain whether the formulation process has reduced the relevant solvent level to within the acceptable amount. Medicinal product should also be tested if a solvent is used during its manufacture.

This guideline does not apply to potential new active substances, excipients, or medicinal products used during the clinical research stages of development, nor does it apply to existing marketed medicinal products.

The guideline applies to all dosage forms and routes of administration. Higher levels of residual solvents may be acceptable in certain cases such as short term (30 days or less) or topical application. Justification for these levels should be made on a case by case basis.

See Appendix 2 for additional background information related to residual solvents.

3. GENERAL PRINCIPLES

3.1. CLASSIFICATION OF RESIDUAL SOLVENTS BY RISK ASSESSMENT

The term “tolerable daily intake” (TDI) is used by the International Program on Chemical Safety (IPCS) to describe exposure limits of toxic chemicals and “acceptable daily intake” (ADI) is used by the World Health Organisation (WHO) and other national and international health authorities and institutes. The new term “permitted daily exposure” (PDE) is defined in the present guideline as a pharmaceutically acceptable intake of residual solvents to avoid confusion of differing values for ADI's of the same substance.

Residual solvents assessed in this guideline are listed in Appendix 1 by common names and structures. They were evaluated for their possible risk to human health and placed into one of three classes as follows:

Class 1 solvents: Solvents to be avoided

Known human carcinogens, strongly suspected human carcinogens, and environmental hazards.

Class 2 solvents: Solvents to be limited

Non-genotoxic animal carcinogens or possible causative agents of other irreversible toxicity such as neurotoxicity or teratogenicity.

Solvents suspected of other significant but reversible toxicities.

Class 3 solvents: Solvents with low toxic potential

Solvents with low toxic potential to man; no health-based exposure limit is needed. Class 3 solvents have PDEs of 50 mg or more per day.

3.2. METHODS FOR ESTABLISHING EXPOSURE LIMITS

The method used to establish permitted daily exposures for residual solvents is presented in Appendix 3. Summaries of the toxicity data that were used to establish limits are published in *Pharmeuropa*, Vol. 9, No. 1, Supplement April 1997.

3.3. OPTIONS FOR DESCRIBING LIMITS OF CLASS 2 SOLVENTS

Two options are available when setting limits for Class 2 solvents.

Option 1: The concentration limits in ppm stated in Table 2 can be used. They were calculated using equation (1) below by assuming a product mass of 10 g administered daily.

$$\text{Concentration (ppm)} = \frac{1000 \times \text{PDE}}{\text{dose}} \quad (1)$$

Here, PDE is given in terms of mg/day and dose is given in g/day.

These limits are considered acceptable for all substances, excipients, or products. Therefore this option may be applied if the daily dose is not known or fixed. If all excipients and active substances in a formulation meet the limits given in Option 1, then these components may be used in any proportion. No further calculation is necessary provided the daily dose does not exceed 10 g. Products that are administered in doses greater than 10 g per day should be considered under Option 2.

Option 2: It is not considered necessary for each component of the medicinal product to comply with the limits given in Option 1. The PDE in terms of mg/day as stated in Table 2 can be used with the known maximum daily dose and equation (1) above to determine the concentration of residual solvent allowed in a medicinal product. Such limits are considered acceptable provided that it has been demonstrated that the residual solvent has been reduced to the practical minimum. The limits should be realistic in relation to analytical precision, manufacturing capability, reasonable variation in the manufacturing process, and the limits should reflect contemporary manufacturing standards.

Option 2 may be applied by adding the amounts of a residual solvent present in each of the components of the medicinal product. The sum of the amounts of solvent per day should be less than that given by the PDE.

Consider an example of the use of Option 1 and Option 2 applied to acetonitrile in a medicinal product. The permitted daily exposure to acetonitrile is 4.1 mg per day; thus, the Option 1 limit is 410 ppm. The maximum administered daily mass of a medicinal product is 5.0 g, and the medicinal product contains two excipients. The composition of the medicinal product and the calculated maximum content of residual acetonitrile are given in the following table.

Component	Amount in formulation	Acetonitrile content	Daily exposure
Active substance	0.3 g	800 ppm	0.24 mg
Excipient 1	0.9 g	400 ppm	0.36 mg
Excipient 2	3.8 g	800 ppm	3.04 mg
Medicinal product	5.0 g	728 ppm	3.64 mg

Excipient 1 meets the Option 1 limit, but the drug substance, excipient 2, and medicinal product do not meet the Option 1 limit. Nevertheless, the product meets the Option 2 limit of 4.1 mg per day and thus conforms to the recommendations in this guideline.

Consider another example using acetonitrile as residual solvent. The maximum administered daily mass of a medicinal product is 5.0 g, and the medicinal product contains two excipients. The composition of the medicinal product and the calculated maximum content of residual acetonitrile is given in the following table.

Component	Amount in formulation	Acetonitrile content	Daily exposure
Active substance	0.3 g	800 ppm	0.24 mg
Excipient 1	0.9 g	2000 ppm	1.80 mg
Excipient 2	3.8 g	800 ppm	3.04 mg
Medicinal product	5.0 g	1016 ppm	5.08 mg

In this example, the product meets neither the Option 1 nor the Option 2 limit according to this summation. The manufacturer could test the medicinal product to determine if the formulation process reduced the level of acetonitrile. If the level of acetonitrile was not reduced during formulation to the allowed limit, then the manufacturer of the medicinal product should take other steps to reduce the amount of acetonitrile in the medicinal product. If all of these steps fail to reduce the level of residual solvent, in exceptional cases the manufacturer could provide a summary of efforts made to reduce the solvent level to meet the guideline value, and provide a risk-benefit analysis to support allowing the product to be utilised containing residual solvent at a higher level.

3.4. ANALYTICAL PROCEDURES

Residual solvents are typically determined using chromatographic techniques such as gas chromatography. Any harmonised procedures for determining levels of residual solvents as described in the pharmacopoeias should be used, if feasible. Otherwise, manufacturers would be free to select the most appropriate validated analytical procedure for a particular application. If only Class 3 solvents are present, a non-specific method such as loss on drying may be used.

Validation of methods for residual solvents should conform to ICH guidelines “Text on Validation of Analytical Procedures” and “Extension of the ICH Text on Validation of Analytical Procedures”.

3.5. REPORTING LEVELS OF RESIDUAL SOLVENTS

Manufacturers of pharmaceutical products need certain information about the content of residual solvents in excipients or active substances in order to meet the criteria of this guideline. The following statements are given as acceptable examples of the information that could be provided from a supplier of excipients or active substances to a pharmaceutical manufacturer. The supplier might choose one of the following as appropriate:

- Only Class 3 solvents are likely to be present. Loss on drying is less than 0.5 per cent.
- Only Class 2 solvents X, Y, ... are likely to be present. All are below the Option 1 limit
(Here the supplier would name the Class 2 solvents represented by X, Y, ...)
- Only Class 2 solvents X, Y, ... and Class 3 solvents are likely to be present. Residual Class 2 solvents are below the Option 1 limit and residual Class 3 solvents are below 0.5 per cent.

If Class 1 solvents are likely to be present, they should be identified and quantified. “Likely to be present” refers to the solvent used in the final manufacturing step and to solvents that are used in earlier manufacturing steps and not removed consistently by a validated process.

If solvents of Class 2 or Class 3 are present at greater than their Option 1 limits or 0.5 per cent, respectively, they should be identified and quantified.

4. LIMITS OF RESIDUAL SOLVENTS

4.1. SOLVENTS TO BE AVOIDED

Solvents in Class 1 should not be employed in the manufacture of active substances, excipients, and medicinal products because of their unacceptable toxicity or their deleterious environmental effect. However, if their use is unavoidable in order to produce a medicinal product with a significant therapeutic advance, then their levels should be restricted as shown in Table 1, unless otherwise justified. 1,1,1-Trichloroethane is included in Table 1 because it is an environmental hazard. The stated limit of 1500 ppm is based on a review of the safety data.

Table 1. – *Class 1 solvents in pharmaceutical products (solvents that should be avoided)*

Solvent	Concentration limit (ppm)	Concern
Benzene	2	Carcinogen
Carbon tetrachloride	4	Toxic and environmental hazard
1,2-Dichloroethane	5	Toxic
1,1-Dichloroethene	8	Toxic
1,1,1-Trichloroethane	1500	Environmental hazard

4.2. SOLVENTS TO BE LIMITED

Solvents in Table 2 should be limited in pharmaceutical products because of their inherent toxicity. PDEs are given to the nearest 0.1 mg/day, and concentrations are given to the nearest 10 ppm. The stated values do not reflect the necessary analytical precision of determination. Precision should be determined as part of the validation of the method.

Table 2. – *Class 2 solvents in pharmaceutical products*

Solvent	PDE (mg/day)	Concentration limit (ppm)
Acetonitrile	4.1	410
Chlorobenzene	3.6	360
Chloroform	0.6	60
Cyclohexane	38.8	3880
1,2-Dichloroethene	18.7	1870
Dichloromethane	6.0	600
1,2-Dimethoxyethane	1.0	100
<i>N,N</i> -Dimethylacetamide	10.9	1090
<i>N,N</i> -Dimethylformamide	8.8	880
1,4-Dioxane	3.8	380
2-Ethoxyethanol	1.6	160
Ethyleneglycol	6.2	620
Formamide	2.2	220
Hexane	2.9	290
Methanol	30.0	3000
2-Methoxyethanol	0.5	50
Methylbutylketone	0.5	50
Methylcyclohexane	11.8	1180
<i>N</i> -Methylpyrrolidone	5.3	530
Nitromethane	0.5	50
Pyridine	2.0	200

Solvent	PDE (mg/day)	Concentration limit (ppm)
Sulfolane	1.6	160
Tetrahydrofuran	7.2	720
Tetralin	1.0	100
Toluene	8.9	890
1,1,2-Trichloroethene	0.8	80
Xylene*	21.7	2170

*usually 60 per cent *m*-xylene, 14 per cent *p*-xylene, 9 per cent *o*-xylene with 17 per cent ethyl benzene

4.3. SOLVENTS WITH LOW TOXIC POTENTIAL

Solvents in Class 3 (shown in Table 3) may be regarded as less toxic and of lower risk to human health. Class 3 includes no solvent known as a human health hazard at levels normally accepted in pharmaceuticals. However, there are no long-term toxicity or carcinogenicity studies for many of the solvents in Class 3. Available data indicate that they are less toxic in acute or short-term studies and negative in genotoxicity studies. It is considered that amounts of these residual solvents of 50 mg per day or less (corresponding to 5000 ppm or 0.5 per cent under Option I) would be acceptable without justification. Higher amounts may also be acceptable provided they are realistic in relation to manufacturing capability and good manufacturing practice.

Table 3. – *Class 3 solvents which should be limited by GMP or other quality-based requirements*

Acetic acid	Heptane
Acetone	Isobutyl acetate
Anisole	Isopropyl acetate
1-Butanol	Methyl acetate
2-Butanol	3-Methyl-1-butanol
Butyl acetate	Methylethylketone
<i>tert</i> -Butylmethyl ether	Methylisobutylketone
Cumene	2-Methyl-1-propanol
Dimethyl sulphoxide	Pentane
Ethanol	1-Pentanol
Ethyl acetate	1-Propanol
Ethyl ether	2-Propanol
Ethyl formate	Propyl acetate
Formic acid	

4.4. SOLVENTS FOR WHICH NO ADEQUATE TOXICOLOGICAL DATA WAS FOUND

The following solvents (Table 4) may also be of interest to manufacturers of excipients, active substances, or medicinal products. However, no adequate toxicological data on which to base a PDE was found. Manufacturers should supply justification for residual levels of these solvents in pharmaceutical products.

Table 4. – *Solvents for which no adequate toxicological data was found*

1,1-Diethoxypropane	Methylisopropylketone
1,1-Dimethoxymethane	Methyltetrahydrofuran
2,2-Dimethoxypropane	Petroleum ether
Isooctane	Trichloroacetic acid
Isopropyl ether	Trifluoroacetic acid

GLOSSARY

Genotoxic carcinogens: Carcinogens which produce cancer by affecting genes or chromosomes.

LOEL: Abbreviation for *lowest-observed effect level*.

Lowest-observed effect level: The lowest dose of substance in a study or group of studies that produces biologically significant increases in frequency or severity of any effects in the exposed humans or animals.

Modifying factor: A factor determined by professional judgement of a toxicologist and applied to bioassay data to relate that data safely to humans.

Neurotoxicity: The ability of a substance to cause adverse effects on the nervous system.

NOEL: Abbreviation for *no-observed-effect level*.

No-observed-effect level: The highest dose of substance at which there are no biologically significant increases in frequency or severity of any effects in the exposed humans or animals.

PDE: Abbreviation for *permitted daily exposure*.

Permitted daily exposure: The maximum acceptable intake per day of residual solvent in pharmaceutical products.

Reversible toxicity: The occurrence of harmful effects that are caused by a substance and which disappear after exposure to the substance ends.

Strongly suspected human carcinogen: A substance for which there is no epidemiological evidence of carcinogenesis but there are positive genotoxicity data and clear evidence of carcinogenesis in rodents.

Teratogenicity: The occurrence of structural malformations in a developing foetus when a substance is administered during pregnancy.

APPENDIX 1. LIST OF SOLVENTS INCLUDED IN THE GUIDELINE

Solvent	Other Names	Structure	Class
Acetic acid	Ethanoic acid	CH_3COOH	Class 3
Acetone	2-Propanone Propan-2-one	CH_3COCH_3	Class 3
Acetonitrile		CH_3CN	Class 2
Anisole	Methoxybenzene		Class 3
Benzene	Benzol		Class 1
1-Butanol	<i>n</i> -Butyl alcohol Butan-1-ol	$\text{CH}_3[\text{CH}_2]_3\text{OH}$	Class 3
2-Butanol	<i>sec</i> -Butyl alcohol Butan-2-ol	$\text{CH}_3\text{CH}_2\text{CH}(\text{OH})\text{CH}_3$	Class 3
Butyl acetate	Acetic acid butyl ester	$\text{CH}_3\text{COO}[\text{CH}_2]_3\text{CH}_3$	Class 3
<i>tert</i> -Butylmethyl ether	2-Methoxy-2-methylpropane	$(\text{CH}_3)_3\text{COCH}_3$	Class 3
Carbon tetrachloride	Tetrachloromethane	CCl_4	Class 1
Chlorobenzene			Class 2
Chloroform	Trichloromethane	CHCl_3	Class 2
Cumene	Isopropylbenzene (1-Methylethyl)benzene		Class 3
Cyclohexane	Hexamethylene		Class 2
1,2-Dichloroethane	<i>sym</i> -Dichloroethane Ethylene dichloride Ethylene chloride	$\text{CH}_2\text{ClCH}_2\text{Cl}$	Class 1
1,1-Dichloroethene	1,1-Dichloroethylene Vinylidene chloride	$\text{H}_2\text{C}=\text{CCl}_2$	Class 1
1,2-Dichloroethene	1,2-Dichloroethylene Acetylene dichloride	$\text{ClHC}=\text{CHCl}$	Class 2
Dichloromethane	Methylene chloride	CH_2Cl_2	Class 2
1,2-Dimethoxyethane	Ethyleneglycol dimethyl ether Monoglyme Dimethyl cellosolve	$\text{H}_3\text{COCH}_2\text{CH}_2\text{OCH}_3$	Class 2
<i>N,N</i> -Dimethylacetamide	DMA	$\text{CH}_3\text{CON}(\text{CH}_3)_2$	Class 2
<i>N,N</i> -Dimethylformamide	DMF	$\text{HCON}(\text{CH}_3)_2$	Class 2
Dimethyl sulphoxide	Methylsulphinylmethane Methyl sulphoxide DMSO	$(\text{CH}_3)_2\text{SO}$	Class 3
1,4-Dioxane	<i>p</i> -Dioxane [1,4]Dioxane		Class 2
Ethanol	Ethyl alcohol	$\text{CH}_3\text{CH}_2\text{OH}$	Class 3
2-Ethoxyethanol	Cellosolve	$\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_2\text{OH}$	Class 2
Ethyl acetate	Acetic acid ethyl ester	$\text{CH}_3\text{COOCH}_2\text{CH}_3$	Class 3

Solvent	Other Names	Structure	Class
Ethyleneglycol	1,2-Dihydroxyethane 1,2-Ethanediol	$\text{HOCH}_2\text{CH}_2\text{OH}$	Class 2
Ethyl ether	Diethyl ether Ethoxyethane 1,1'-Oxybisethane	$\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_3$	Class 3
Ethyl formate	Formic acid ethyl ester	$\text{HCOOCH}_2\text{CH}_3$	Class 3
Formamide	Methanamide	HCONH_2	Class 2
Formic acid		HCOOH	Class 3
Heptane	<i>n</i> -Heptane	$\text{CH}_3[\text{CH}_2]_5\text{CH}_3$	Class 3
Hexane	<i>n</i> -Hexane	$\text{CH}_3[\text{CH}_2]_4\text{CH}_3$	Class 2
Isobutyl acetate	Acetic acid isobutyl ester	$\text{CH}_3\text{COOCH}_2\text{CH}(\text{CH}_3)_2$	Class 3
Isopropyl acetate	Acetic acid isopropyl ester	$\text{CH}_3\text{COOCH}(\text{CH}_3)_2$	Class 3
Methanol	Methyl alcohol	CH_3OH	Class 2
2-Methoxyethanol	Methyl cellosolve	$\text{CH}_3\text{OCH}_2\text{CH}_2\text{OH}$	Class 2
Methyl acetate	Acetic acid methyl ester	$\text{CH}_3\text{COOCH}_3$	Class 3
3-Methyl-1-butanol	Isoamyl alcohol Isopentyl alcohol 3-Methylbutan-1-ol	$(\text{CH}_3)_2\text{CHCH}_2\text{CH}_2\text{OH}$	Class 3
Methylbutylketone	2-Hexanone Hexan-2-one	$\text{CH}_3[\text{CH}_2]_3\text{COCH}_3$	Class 2
Methylcyclohexane	Cyclohexylmethane		Class 2
Methylethylketone	2-Butanone MEK Butan-2-one	$\text{CH}_3\text{CH}_2\text{COCH}_3$	Class 3
Methylisobutylketone	4-Methylpentan-2-one 4-Methyl-2-pentanone MIBK	$\text{CH}_3\text{COCH}_2\text{CH}(\text{CH}_3)_2$	Class 3
2-Methyl-1-propanol	Isobutyl alcohol 2-Methylpropan-1-ol	$(\text{CH}_3)_2\text{CHCH}_2\text{OH}$	Class 3
<i>N</i> -Methylpyrrolidone	1-Methylpyrrolidin-2-one 1-Methyl-2-pyrrolidinone		Class 2
Nitromethane		CH_3NO_2	Class 2
Pentane	<i>n</i> -Pentane	$\text{CH}_3[\text{CH}_2]_3\text{CH}_3$	Class 3
1-Pentanol	Amyl alcohol Pentan-1-ol Pentyl alcohol	$\text{CH}_3[\text{CH}_2]_3\text{CH}_2\text{OH}$	Class 3
1-Propanol	Propan-1-ol Propyl alcohol	$\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$	Class 3
2-Propanol	Propan-2-ol Isopropyl alcohol	$(\text{CH}_3)_2\text{CHOH}$	Class 3
Propyl acetate	Acetic acid propyl ester	$\text{CH}_3\text{COOCH}_2\text{CH}_2\text{CH}_3$	Class 3
Pyridine			Class 2
Sulfonane	Tetrahydrothiophene 1,1-dioxide		Class 2

Solvent	Other Names	Structure	Class
Tetrahydrofuran	Tetramethylene oxide Oxacyclopentane		Class 2
Tetralin	1,2,3,4-Tetrahydronaphthalene		Class 2
Toluene	Methylbenzene		Class 2
1,1,1-Trichloroethane	Methylchloroform	CH_3CCl_3	Class 1
1,1,2-Trichloroethene	Trichloroethene	$\text{HClC}=\text{CCl}_2$	Class 2
Xylene*	Dimethylbenzene Xylol		Class 2

*usually 60 per cent *m*-xylene, 14 per cent *p*-xylene, 9 per cent *o*-xylene with 17 per cent ethyl benzene.

APPENDIX 2. ADDITIONAL BACKGROUND

A2.1. ENVIRONMENTAL REGULATION OF ORGANIC VOLATILE SOLVENTS

Several of the residual solvents frequently used in the production of pharmaceuticals are listed as toxic chemicals in Environmental Health Criteria (EHC) monographs and the Integrated Risk Information System (IRIS). The objectives of such groups as the International Programme on Chemical Safety (IPCS), the United States Environmental Protection Agency (USEPA) and the United States Food and Drug Administration (USFDA) include the determination of acceptable exposure levels. The goal is protection of human health and maintenance of environmental integrity against the possible deleterious effects of chemicals resulting from long-term environmental exposure. The methods involved in the estimation of maximum safe exposure limits are usually based on long-term studies. When long-term study data are unavailable, shorter term study data can be used with modification of the approach such as use of larger safety factors. The approach described therein relates primarily to long-term or life-time exposure of the general population in the ambient environment, i.e. ambient air, food, drinking water and other media.

A2.2. RESIDUAL SOLVENTS IN PHARMACEUTICALS

Exposure limits in this guideline are established by referring to methodologies and toxicity data described in EHC and IRIS monographs. However, some specific assumptions about residual solvents to be used in the synthesis and formulation of pharmaceutical products should be taken into account in establishing exposure limits. They are:

- 1) Patients (not the general population) use pharmaceuticals to treat their diseases or for prophylaxis to prevent infection or disease.
- 2) The assumption of life-time patient exposure is not necessary for most pharmaceutical products but may be appropriate as a working hypothesis to reduce risk to human health.
- 3) Residual solvents are unavoidable components in pharmaceutical production and will often be a part of medicinal products.
- 4) Residual solvents should not exceed recommended levels except in exceptional circumstances.

5) Data from toxicological studies that are used to determine acceptable levels for residual solvents should have been generated using appropriate protocols such as those described for example, by OECD and the FDA Red Book.

APPENDIX 3. METHODS FOR ESTABLISHING EXPOSURE LIMITS

The Gaylor-Kodell method of risk assessment (Gaylor, D. W. and Kodell, R. L. Linear Interpolation algorithm for low dose assessment of toxic substance. *J. Environ. Pathology*, 4, 305, 1980) is appropriate for Class 1 carcinogenic solvents. Only in cases where reliable carcinogenicity data are available should extrapolation by the use of mathematical models be applied to setting exposure limits. Exposure limits for Class 1 solvents could be determined with the use of a large safety factor (i.e., 10 000 to 100 000) with respect to the no-observed-effect level (NOEL). Detection and quantification of these solvents should be by state-of-the-art analytical techniques.

Acceptable exposure levels in this guideline for Class 2 solvents were established by calculation of PDE values according to the procedures for setting exposure limits in pharmaceuticals (*Pharmacopeial Forum*, Nov-Dec 1989), and the method adopted by IPCS for Assessing Human Health Risk of Chemicals (*Environmental Health Criteria 170*, WHO, 1994). These methods are similar to those used by the USEPA (IRIS) and the USFDA (*Red Book*) and others. The method is outlined here to give a better understanding of the origin of the PDE values. It is not necessary to perform these calculations in order to use the PDE values tabulated in Section 4 of this document.

PDE is derived from the no-observed-effect level (NOEL), or the lowest-observed effect level (LOEL), in the most relevant animal study as follows:

$$\text{PDE} = \frac{\text{NOEL} \times \text{Weight Adjustment}}{\text{F}_1 \times \text{F}_2 \times \text{F}_3 \times \text{F}_4 \times \text{F}_5}$$

The PDE is derived preferably from a NOEL. If no NOEL is obtained, the LOEL may be used. Modifying factors proposed here, for relating the data to humans, are the same kind of “uncertainty factors” used in Environmental Health Criteria (*Environmental Health Criteria 170*, World Health Organisation, Geneva, 1994), and “modifying factors” or

“safety factors” in *Pharmacopoeial Forum*. The assumption of 100 per cent systemic exposure is used in all calculations regardless of route of administration.

The modifying factors are as follows:

F1 = A factor to account for extrapolation between species

F1 = 2 for extrapolation from dogs to humans

F1 = 2.5 for extrapolation from rabbits to humans

F1 = 3 for extrapolation from monkeys to humans

F1 = 5 for extrapolation from rats to humans

F1 = 10 for extrapolation from other animals to humans

F1 = 12 for extrapolation from mice to humans

F1 takes into account the comparative surface area: body weight ratios for the species concerned and for man. Surface area (S) is calculated as:

$$S = km^{0.67}$$

in which m = body mass, and the constant k has been taken to be 10. The body weight used in the equation are those shown below in Table A3-1.

Table A3-1. – Values used in the calculations in this document

Rat body weight	425 g
Pregnant rat body weight	330 g
Mouse body weight	28 g
Pregnant mouse body weight	30 g
Guinea-pig body weight	500 g
Rhesus monkey body weight	2.5 kg
Rabbit body weight (pregnant or not)	4 kg
Beagle dog body weight	11.5 kg
Rat respiratory volume	290 l/day
Mouse respiratory volume	43 l/day
Rabbit respiratory volume	1440 l/day
Guinea-pig respiratory volume	430 l/day
Human respiratory volume	28800 l/day
Dog respiratory volume	9000 l/day
Monkey respiratory volume	1150 l/day
Mouse water consumption	5 ml/day
Rat water consumption	30 ml/day
Rat food consumption	30 g/day

F2 = A factor of 10 to account for variability between individuals. A factor of 10 is generally given for all organic solvents, and 10 is used consistently in this guideline.

F3 = A variable factor to account for toxicity studies of short-term exposure.

F3 = 1 for studies that last at least one half-lifetime (1 year for rodents or rabbits; 7 years for cats, dogs and monkeys).

F3 = 1 for reproductive studies in which the whole period of organogenesis is covered.

F3 = 2 for a 6 month study in rodents, or a 3.5 year study in non-rodents.

F3 = 5 for a 3 month study in rodents, or a 2 year study in non-rodents.

F3 = 10 for studies of a shorter duration.

In all cases, the higher factor has been used for study durations between the time points, e.g. a factor of 2 for a 9 month rodent study.

F4 = A factor that may be applied in cases of severe toxicity, e.g. non-genotoxic carcinogenicity, neurotoxicity or teratogenicity. In studies of reproductive toxicity, the following factors are used:

F4 = 1 for foetal toxicity associated with maternal toxicity

F4 = 5 for foetal toxicity without maternal toxicity

F4 = 5 for a teratogenic effect with maternal toxicity

F4 = 10 for a teratogenic effect without maternal toxicity

F5 = A variable factor that may be applied if the no-effect level was not established.

When only a LOEL is available, a factor of up to 10 can be used depending on the severity of the toxicity.

The weight adjustment assumes an arbitrary adult human body weight for either sex of 50 kg. This relatively low weight provides an additional safety factor against the standard weights of 60 kg or 70 kg that are often used in this type of calculation. It is recognised that some adult patients weigh less than 50 kg; these patients are considered to be accommodated by the built-in safety factors used to determine a PDE. If the solvent was present in a formulation specifically intended for paediatric use, an adjustment for a lower body weight would be appropriate.

As an example of the application of this equation, consider the toxicity study of acetonitrile in mice that is summarised in *Pharmeuropa*, Vol. 9. No. 1, Supplement, April 1997, page S24. The NOEL is calculated to be 50.7 mg kg⁻¹ day⁻¹. The PDE for acetonitrile in this study is calculated as follows:

$$\text{PDE} = \frac{50.7 \text{ mg kg}^{-1} \text{ day}^{-1} \times 50 \text{ kg}}{12 \times 10 \times 5 \times 1 \times 1} = 4.22 \text{ mg day}^{-1}$$

In this example,

F1 = 12 to account for the extrapolation from mice to humans

F2 = 10 to account for differences between individual humans

F3 = 5 because the duration of the study was only 13 weeks

F4 = 1 because no severe toxicity was encountered

F5 = 1 because the no-effect level was determined

The equation for an ideal gas, $PV = nRT$, is used to convert concentrations of gases used in inhalation studies from units of ppm to units of mg/l or mg/m³. Consider as an example the rat reproductive toxicity study by inhalation of carbon tetrachloride (molecular weight 153.84) summarised in *Pharmeuropa*, Vol. 9, No. 1, Supplement, April 1997, page S9.

$$\begin{aligned}\frac{n}{V} &= \frac{P}{RT} = \frac{300 \times 10^{-6} \text{ atm} \times 153\,840 \text{ mg mol}^{-1}}{0.082 \text{ l atm K}^{-1} \text{ mol}^{-1} \times 298 \text{ K}} \\ &= \frac{46.15 \text{ mg}}{24.45 \text{ l}} = 1.89 \text{ mg/l}\end{aligned}$$

The relationship 1000 litres = 1 m³ is used to convert to mg/m³.

01/2005:50500

5.5. ALCOHOLIMETRIC TABLES

The general formula agreed by the Council of the European Communities in its Directive of 27 July 1976 on alcoholimetry served as the basis for establishing the following tables.

% V/V	% m/m	ρ_{20} (kg/m ³)
0.0	0.0	998.20
0.1	0.08	998.05
0.2	0.16	997.90
0.3	0.24	997.75
0.4	0.32	997.59
0.5	0.40	997.44
0.6	0.47	997.29
0.7	0.55	997.14

5.6. ASSAY OF INTERFERONS

The following chapter is published for information.

1. INTRODUCTION

Monographs on human interferons generally contain a bioassay based on the inhibitory activity of the interferon on the cytopathic action of a virus on a cell line in culture. In most cases, however, the virus, cell line and the assay details are not specified, in order to allow the appropriate flexibility, where the monograph covers more than one sub-class of interferon.

The present text is intended to provide outline information for the analyst on how to design, optimise and validate such an assay once an appropriate combination of cell line and cytopathic virus has been identified. A detailed procedure for a particular cytopathic antiviral assay is described as an example of a suitable method, together with information on other virus-cell line combinations and guidance on how to adapt and validate the procedure for these other combinations.

2. ANTIVIRAL (CYTOPATHIC EFFECT REDUCTION) ASSAYS

The antiviral assay of human interferons is based on the induction of a cellular response in human cells, which prevents or reduces the cytopathic effect of an infectious virus. The potency of interferon is estimated by comparing its protective effect against a viral cytopathic effect with the same effect of the appropriate reference preparation calibrated in International Units.

3. INTERFERON ASSAY USING Hep2c CELLS AND INFECTIOUS ENCEPHALOMYOCARDITIS VIRUS

The antiviral assay of human interferons described is of the cytopathic effect reduction type. It uses human Hep2c cells infected by encephalomyocarditis virus (EMCV) to measure the potencies of different human interferon test preparations. This assay has been used in three World Health Organisation (WHO) international collaborative studies of candidate International Standards for human interferon alpha, human interferon beta and human interferon gamma and has repeatedly been demonstrated to be sensitive, reliable and reproducible for potency estimations of the different types of human interferon.

For the culture of mammalian cells, all procedures are carried out using standard operating procedures for the maintenance of such cell lines in culture. Volumes of reagents are indicated for cell cultures carried out in 75 cm² flasks. Other types of containers (flasks or plates) may be used but volumes must be adapted accordingly.

3.1. MAINTENANCE AND PREPARATION OF *Her2c* CELLS

Hep2c cells are maintained and passaged in culture medium A.

Cells are stored as frozen stocks using standard operating procedures. Growing cells may be maintained in culture up to a permitted passage number of 30, after which new cultures are established from frozen stocks.

At the beginning of the assay procedure, harvest the cells from the flasks showing 90 per cent confluent monolayers using the trypsin-treatment procedure described below.

- Remove the culture medium from the flasks.
- To each flask, add 5 ml of trypsin solution heated at 37 °C (a trypsin stock solution contains 4 mg/ml of *trypsin R* and 4 mg/ml of *sodium edetate R*; immediately before use, dilute 50 times with phosphate buffered saline). Swirl the capped flask to wash the cell monolayer. Remove the excess of trypsin solution.
- Incubate the flasks for 5 min to 10 min at 37 °C. Microscopically or visually observe the cells for signs of detachment. When viewed microscopically, the cells appear rounded up or detached and free-floating. Shake the flask vigorously to detach all the cells, add approximately 5 ml of culture medium A. Shake vigorously to yield a suspension of single cells.
- To prepare the cell suspensions for the assay procedure, carefully disperse the cells by pipetting up and down to disrupt cell aggregates, count the cells and resuspend at a concentration of 6×10^5 cells/ml.

3.2. PROPAGATION OF ENCEPHALOMYOCARDITIS VIRUS

Encephalomyocarditis virus is propagated in mouse L-929 cells in order to produce a stock of progeny virus. L-929 cells are maintained by trypsin treatment and passage as described for Hep2c cells (*NOTE: it may be necessary to substitute neonatal calf serum with foetal bovine serum if the cells show poor growth*).

Take several flasks containing confluent cultures of L-929 cells. Pour off the medium from the flasks. Inoculate with 2 ml of the EMCV suspension appropriately diluted in culture medium B so that it contains approximately 2.5×10^8 plaque forming units (PFU) per millilitre. Each flask will contain $4-6 \times 10^7$ L-929 cells and therefore the multiplicity of infection (m.o.i.) will be approximately 10 PFU/cell. Carefully swirl the virus suspension over the entire cell monolayer and return the flasks to the incubator for approximately 1 h. Maintain the medium at pH 7.4 to 7.8.

After adsorption of the EMCV, add approximately 40 ml of culture medium B to each flask and return the flasks to the incubator at 37 °C for about 30 h. Maintain the medium at pH 7.4 to 7.8 to obtain a maximum virus yield. Remove the culture fluid and store at approximately 40 °C.

Place the flasks at –20 °C to freeze the cell monolayer. Then thaw to room temperature. Add approximately 5 ml of culture medium and shake the flask to disrupt the cell walls. Transfer the contents of each flask to the container of culture fluid. Transfer the culture fluid containing the EMCV to 50 ml plastic centrifuge tubes and centrifuge at approximately 500 *g* for about 10 min to remove cell debris. Dispense the clarified culture fluid into glass screw-capped bottles, in quantities of 20 ml, 10 ml, 5 ml, 1 ml, 0.5 ml or 0.2 ml, as appropriate. Store at –70 °C. Larger volumes can be thawed, dispensed into smaller quantities and re-frozen when required. The EMCV stock will retain its original titre if stored permanently at approximately –70 °C, but repeated freeze-thaw cycles or storage at higher temperatures, e.g. at approximately –20 °C, results in progressive loss of titre.

3.3. ASSAY PROCEDURE

3.3.1. Determination of the dose-response range

Preparation of the solutions

Dilute the appropriate standard for interferon (for example a specific WHO sub-type interferon standard) in culture medium A, in 10-fold dose increments, to give doses covering the range of 1000 - 0.001 IU/ml. Carry out the assay procedure in 96-well microtitre plates. To each well add 100 µl of culture medium A. Add approximately 100 µl of each dilution of the reference preparation to each well except for those intended for virus controls. Using a multichannel pipette set at 100 µl, mix the contents of the wells.

Dispensing of the cell suspension

Pour the cell suspension of Hep2c cells, which has been adjusted to contain approximately 6×10^5 cells/ml of culture medium A, into a plastic Petri-dish. Dispense the cell suspension from the Petri-dish into each well of the microtitre plates, using a multichannel pipette set at 100 µl. Incubate the plates for about 24 h in an incubator set at 37 °C and 5 per cent CO₂.

Viral infection

At this stage, using an inverted microscope, check that the monolayers of Hep2c cells are confluent, that they show a relatively even distribution of cells, that they have correct morphology and that they are healthy.

Remove most of the culture medium from the wells by inverting the plate and shaking it and blotting on a paper towel (proceed in an identical way when discarding fluids from micro-titre plates as described later). Dilute the EMCV stock with fresh culture medium A to a titre of approximately 3×10^7 PFU/ml (*NOTE: each plate requires approximately 20 ml of diluted virus, plus 5 per cent to 10 per cent of extra volume*). Dispense the diluted suspension from a 9 cm sterile Petri-dish using a multichannel pipette set at 200 µl to all wells including virus controls, but excluding cell controls. Add approximately 200 µl of culture medium A without virus to each of the cell control wells.

Return the plates to the incubator set at 37 °C and 5 per cent CO₂ for approximately 24 h.

Staining

Examine the plates microscopically to check that the EMCV has caused a cytopathic effect (c.p.e.) in the virus controls. The time interval for maximum c.p.e. may vary from one assay to the next because of inherent variation of Hep2c cells to virus challenge over a given period of continuous cultivation.

Remove most of the culture medium from the wells by discarding into an appropriate decontaminating solution (sodium hypochlorite is suitable). Dispense *phosphate buffered saline pH 7.4 R* into each well. Discard the *phosphate buffered saline pH 7.4 R* into a decontaminating solution. Dispense into each well 150 µl of staining solution. Stain the cells for approximately 30 min at room temperature. Discard the staining solution into a decontaminating solution. Dispense approximately 150 µl of fixing solution. Fix for 10 min at room temperature. Discard the fixing solution into a decontaminating solution and wash the cell monolayers by immersing the assay plates in a plastic box containing running water. Discard the water and superficially dry the plates with paper towels. Dry the assay plates at 20 °C to 37 °C until all moisture has evaporated.

Add 150 µl of 0.1 M sodium hydroxide to each well. Elute the stain by gentle agitation of the plates or by hitting them against the palm of the hand. Make sure that the stain is evenly distributed in all wells before making spectrophotometric readings.

Read the absorbance at 610 nm to 620 nm, using a microtitre plate reader, taking as a blank a well or a column of wells containing no cells and approximately 150 µl of 0.1 M sodium hydroxide.

Estimate the concentrations of interferon standard that give the maximum and minimum reduction of cytopathic effect. This is the dose response corresponding to the working range of the assay.

3.3.2. Assay procedure

Carry out the assay as described above, using:

- as test solutions, the substance to be examined, diluted in two-fold increments with culture medium A to give nominal concentrations covering the working range of the assay,
- as reference solutions, the appropriate standard for interferon (for example, a specific WHO sub-type interferon) in culture medium A, diluted in two-fold increments to give nominal concentrations covering the working range of the assay.

3.3.3. Data analysis

Results of the cytopathic effect reduction assay generally fit a sigmoidal dose-response curve, when the interferon concentration (the log of the reciprocal of the interferon dilution) is plotted versus stain absorbance.

Plot the interferon concentration (log reciprocal of dilution) versus the stain absorbance for the interferon reference preparation and for the interferon test solutions. Using the linear portion of the curve, calculate the concentration of interferon in the sample by comparing the responses for test and reference solutions, using the usual statistical methods for a parallel line assay.

4. VALIDATION OF OTHER PROCEDURES

4.1. CHOICE OF CELL LINE AND VIRUS

A number of other combinations of cell line and virus have been used in anti-viral assays for interferons. For example, EMCV has been used in combination with the A549 epithelial lung carcinoma cell line, Semliki Forest virus or Sindbis virus have been used with human fibroblasts, and vesicular stomatitis virus has been used with either human diploid fibroblasts, the human amnion WISH cell line or the Madin-Darby bovine kidney cell line. In each case the choice of the cell line/virus combination is usually based on that which gives the most sensitive response to the interferon preparation to be assayed, and gives parallel responses when comparing the test preparation and interferon standard.

4.2. CHOICE OF RESPONSE

The staining procedure described above measures remaining viable cells. A number of other responses have been used, including methyl violet or crystal violet staining, or the thiazolyl blue (MTT) conversion procedure. In each case, the method is selected on the basis of producing a suitably linear and sensitive relationship between response colour and viable cell count.

4.3. STATISTICAL VALIDATION

As with all parallel line bioassays, the assay must satisfy the usual statistical criteria of linearity of response, parallelism and variance.

4.4. VALIDATION OF ASSAY LAYOUT

As with all microtitre plate assay procedures, attention must be given to validating the assay layout. In particular, bias due to non-random pipetting order or plate edge effects must be investigated and eliminated, by randomising the assay layout, or by avoiding the use of edge wells.

REAGENTS AND CULTURE MEDIA

Culture medium A (10 per cent neonatal calf serum)

RPMI 1640 culture medium, supplemented with antibiotics if necessary (penicillin 10 000 IU/ml; streptomycin 10 ng/ml)	450 ml
L-Glutamine, 200 mM, sterile	5 ml
Neonatal calf serum	50 ml

Culture medium B (2 per cent foetal bovine serum)

RPMI 1640 culture medium, supplemented with antibiotics if necessary (penicillin 10 000 IU/ml; streptomycin 10 ng/ml)	490 ml
L-Glutamine, 200 mM, sterile	5 ml
Foetal bovine serum	10 ml

Staining solution

Naphthalene black	0.5 g
Acetic acid, glacial	90 ml
Sodium acetate, anhydrous	8.2 g
Water to produce	1000 ml

Fixing solution

Formaldehyde, 40 per cent	100 ml
Acetic acid, glacial	90 ml
Sodium acetate, anhydrous	8.2 g
Water to produce	1000 ml

5.7. TABLE OF PHYSICAL CHARACTERISTICS OF RADIONUCLIDES MENTIONED IN THE EUROPEAN PHARMACOPOEIA

The following table is given to complete the general monograph on *Radiopharmaceutical preparations (0125)*.

The values are obtained from the database of the National Nuclear Data Center (NNDC) at Brookhaven National Laboratory, Upton. N.Y., USA, directly accessible via Internet at the address: "http://www.nndc.bnl.gov/nndc/nudat/radform.html".

In case another source of information is preferred (more recent values), this source is explicitly mentioned.

Other data sources:

* DAMRI (Département des Applications et de la Métrologie des Rayonnements Ionisants, CEA Gif-sur-Yvette, France),

The uncertainty of the half-lives are given in parentheses. In principle the digits in parentheses are the standard uncertainty of the corresponding last digits of the indicated numerical value "Guide to the Expression of Uncertainty in measurement", International Organisation for Standardisation (ISO), 1993, ISBN 92-67-10188-9).

The following abbreviations are used:

e_A = Auger electrons,

ce = conversion electrons,

β^- = electrons,

β^+ = positrons,

γ = gamma rays,

X = X-rays.

Radionuclide	Half-life	Electronic emission			Photon emission

5.8. PHARMACOPOEIAL HARMONISATION

This general chapter is included for guidance of users. It provides information on the degree of harmonisation and consequently interchangeability of various general chapters and monographs of the European Pharmacopoeia and those of the Japanese Pharmacopoeia and United States Pharmacopoeia. The chapter does not affect in any way the status of the monographs and general chapters as the authoritative reference in any case of doubt or dispute where compliance with the European Pharmacopoeia is required.

The European Pharmacopoeia Commission recognises the utility of working with other pharmacopoeial bodies to develop harmonised monographs and general chapters. Such harmonisation is fully compatible with the declared aims of the Commission and has benefits of different kinds, notably the simplification and rationalisation of quality control methods and licensing procedures. Such harmonisation also enhances the benefits of the work of the International Conference on Harmonisation (ICH) and the Veterinary International Co-operation on Harmonisation (VICH) since some of the guidelines developed depend on pharmacopoeial general chapters for their application.

Work on harmonisation is carried out by a well-defined but informal process in the Pharmacopoeial Discussion Group (PDG), in which the European Pharmacopoeia, the Japanese

Pharmacopoeia and the United States Pharmacopoeia are associated. Information will be given in subsequent revised versions of this general chapter on items that have been dealt with by the PDG.

Where harmonisation of general chapters is carried out, the aim is to arrive at interchangeable methods or requirements so that demonstration of compliance using a general chapter from one of the three pharmacopoeias implies that the same result would be obtained using the general chapter of either of the other pharmacopoeias. If residual differences remain in harmonised general chapters, information will be given in subsequent versions of this general chapter.

Where harmonisation of monographs is carried out, the aim is to arrive at identical requirements for all attributes of a product. For some products, it can be extremely difficult to achieve complete harmonisation, for example because of differences in legal status and interpretation. It has therefore appeared to the PDG worthwhile to approve and publish monographs in which as many attributes as possible are harmonised. Information on any non-harmonised attributes will be included in subsequent versions of this general chapter.

The three Pharmacopoeias have undertaken not to make unilateral changes to harmonised monographs and general chapters but rather to apply the agreed revision procedure whereby all partners adopt a revision simultaneously.

01/2005:50900

5.9. POLYMORPHISM

Polymorphism (or crystal polymorphism) is a phenomenon related to the solid state; it is the ability of a compound in the solid state to exist in different crystalline forms having the same chemical composition. Substances that exist in a non-crystalline solid state are said to be amorphous.

When this phenomenon is observed for a chemical element (for example, sulphur), the term allotropy is used instead of polymorphism.

The term pseudopolymorphism is used to describe solvates (including hydrates), where a solvent is present in the crystal matrix in stoichiometric proportions; the term may also be extended to include compounds where the solvent is trapped in the matrix in variable proportions. However the term pseudopolymorphism is ambiguous because of its use in different circumstances. It is therefore preferable to use only the terms “solvates” and “hydrates”.

Where a monograph indicates that a substance shows polymorphism, this may be true crystal polymorphism, occurrence of solvates, allotropy or occurrence of the amorphous form.

The identity of chemical composition implies that all crystalline and amorphous forms of a given species have the same chemical behaviour in solution or as a melt; in contrast, their physico-chemical and physical characteristics (solubility, hardness, compressibility, density, melting point, etc.), and therefore their reactivity and bioavailability may be different at the solid state.

When a compound shows polymorphism, the form for which the free enthalpy is lowest at a given temperature and pressure is the most thermodynamically stable. The other forms are said to be in a metastable state. At normal temperature and pressure, a metastable form may remain unchanged or may change to a thermodynamically more stable form.

If there are several crystalline forms, one form is thermodynamically more stable at a given temperature and pressure. A given crystalline form may constitute a phase that can reach equilibrium with other solid phases and with the liquid and gas phases.

If each crystalline form is the more stable within a given temperature range, the change from one form to another is reversible and is said to be enantiotropic. The change from

one phase to another is a univariate equilibrium, so that at a given pressure this state is characterised by a transition temperature. However, if only one of the forms is stable over the entire temperature range, the change is irreversible or monotropic.

Different crystalline forms or solvates may be produced by varying the crystallisation conditions (temperature, pressure, solvent, concentration, rate of crystallisation, seeding of the crystallisation medium, presence and concentration of impurities, etc.).

The following techniques may be used to study polymorphism:

- X-ray diffraction of powders,
- X-ray diffraction of single crystals,
- thermal analysis (2.2.34) (differential scanning calorimetry, thermogravimetry, thermomicroscopy),
- microcalorimetry,
- moisture absorption analysis,
- optical and electronic microscopy,
- solid-state nuclear magnetic resonance,
- infrared absorption spectrophotometry (2.2.24),
- Raman spectrometry (2.2.48),
- measurement of solubility and intrinsic dissolution rate,
- density measurement.

These techniques are often complementary and it is indispensable to use several of them.

Pressure/temperature and energy/temperature diagrams based on analytical data are valuable tools for fully understanding the energetic relationship (enantiotropism, monotropism) and the thermodynamic stability of the individual modifications of a polymorphic compound.

For solvates, differential scanning calorimetry and thermogravimetry are preferable, combined with measurements of solubility, intrinsic dissolution rate and X-ray diffraction.

For hydrates, water sorption/desorption isotherms are determined to demonstrate the zones of relative stability.

In general, hydrates are less soluble in water than anhydrous forms, and likewise solvates are less soluble in their solvent than unsolvated forms.

5.10. CONTROL OF IMPURITIES IN SUBSTANCES FOR PHARMACEUTICAL USE

Preamble

The monographs of the European Pharmacopoeia on substances for pharmaceutical use are designed to ensure acceptable quality for users. The role of the Pharmacopoeia in public health protection requires that adequate control of impurities be provided by monographs. The quality required is based on scientific, technical and regulatory considerations.

Requirements concerning impurities are given in specific monographs and in the general monograph *Substances for pharmaceutical use (2034)*. Specific monographs and the general monograph are complementary: specific monographs prescribe acceptance criteria for impurities whereas the general monograph deals with the need for qualification, identification and reporting of any organic impurities that occur in *active substances*.

The thresholds for reporting, identification and qualification contained in the general monograph *Substances for pharmaceutical use (2034)* apply to all related substances. However, if a monograph does not contain a related substances test based on a quantitative method, any new impurities occurring above a threshold may be overlooked since the test is not capable to detect those impurities.

The provisions of the Related substances section of the general monograph *Substances for pharmaceutical use (2034)*, notably those concerning thresholds, do not apply to excipients; also excluded from the provisions of this section are: biological and biotechnological products; peptides; oligonucleotides; radiopharmaceuticals; fermentation products and semisynthetic products derived therefrom; herbal products and crude products of animal and plant origin. Although the thresholds stated in the general monograph do not apply, the general concepts of reporting, identification (wherever possible) and qualification of impurities are equally valid for these classes.

Basis for the elaboration of monographs of the European Pharmacopoeia

European Pharmacopoeia monographs are elaborated on substances that are present in medicinal products that have been authorised by the competent authorities of Parties to the *European Pharmacopoeia Convention*. Consequently, these monographs do not necessarily cover all sources of substances for pharmaceutical use on the world market.

Organic and inorganic impurities present in those substances that have been evaluated by the competent authorities are qualified with respect to safety at the maximum authorised content (at the maximum daily dose) unless new safety data that become available following evaluation justify lower limits.

European Pharmacopoeia monographs on substances for pharmaceutical use are elaborated by groups of experts and working parties collaborating with national pharmacopoeia authorities, the competent authorities for marketing authorisation, national control laboratories and the European Pharmacopoeia laboratory; they are also assisted by the producers of the substances and/or the pharmaceutical manufacturers that use these substances.

Control of impurities in substances for pharmaceutical use

The quality with respect to impurities is controlled by a set of tests within a monograph. These tests are intended to cover

organic and inorganic impurities that are relevant in view of the sources of active substances in authorised medicinal products.

Control of residual solvents is provided by the general monograph *Substances for pharmaceutical use (2034)* and general chapter 5.4. *Residual solvents*. The certificate of suitability of a monograph of the European Pharmacopoeia for a given source of a substance indicates the residual solvents that are controlled together with the specified acceptance criteria and the validated control method where this differs from those described in general chapter 2.4.24. *Identification and control of residual solvents*.

Monographs on organic chemicals usually have a test entitled "Related substances" that covers relevant organic impurities. This test may be supplemented by specific tests where the general test does not control a given impurity or where there are particular reasons (for example, safety reasons) for requiring special control.

Where a monograph has no Related substances (or equivalent) test but only specific tests, the user of a substance must nevertheless ensure that there is suitable control of organic impurities; those occurring above the identification threshold are to be identified (wherever possible) and, unless justified, those occurring above the qualification threshold are to be qualified (see also under Recommendations to users of monographs of active substances).

Where the monograph covers substances with different impurity profiles, it may have a single related substances test to cover all impurities mentioned in the Impurities section or several tests may be necessary to give control of all known profiles. Compliance may be established by carrying out only the tests relevant to the known impurity profile for the source of the substance.

Instructions for control of impurities may be included in the Production section of a monograph, for example where the only analytical method appropriate for the control of a given impurity is to be performed by the manufacturer since the method is too technically complex for general use or cannot be applied to the final drug substance and/or where validation of the production process (including the purification step) will give sufficient control.

Impurities section in monographs on active substances

The Impurities section in a monograph includes impurities (chemical structure and name wherever possible), which are usually organic, that are known to be detected by the tests prescribed in the monograph. It is based on information available at the time of elaboration or revision of the monograph and is not necessarily exhaustive. The section includes specified impurities and, where so indicated, other detectable impurities.

Specified impurities have an acceptance criterion not greater than that authorised by the competent authorities.

Other detectable impurities are potential impurities with a defined structure but not known to be normally present above the identification threshold in substances used in medicinal products that have been authorised by the competent authorities of Parties to the Convention. They are given in the Impurities section for information.

Where an impurity other than a specified impurity is found in an active substance it is the responsibility of the user of the substance to check whether it has to be identified/qualified, depending on its content, nature, maximum daily dose and relevant identification/qualification threshold, in accordance with the general monograph on *Substances for pharmaceutical use (2034)*, Related substances section.

It should be noted that specific thresholds are applied to substances exclusively for veterinary use.

Interpretation of the test for related substances in the monographs on active substances

A specific monograph on a substance for pharmaceutical use is to be read and interpreted in conjunction with the general monograph on *Substances for pharmaceutical use (2034)*.

Where a general acceptance criterion for impurities (“any other impurity”, “other impurities”, “any impurity”) equivalent to a nominal content greater than the applicable identification threshold (see the general monograph on *Substances for pharmaceutical use (2034)*) is prescribed, this is valid only for specified impurities mentioned in the Impurities section. The need for identification (wherever possible), reporting, specification and qualification of other impurities that occur must be considered according to the requirements of the general monograph. It is the responsibility of the user of the substance to determine the validity of the acceptance criteria for impurities not mentioned in the Impurities section and for those indicated as other detectable impurities.

The following examples are given as an aid in the interpretation of acceptance criteria for impurities in specific monographs. The examples correspond to different styles currently used in monographs pending harmonisation in a future edition.

Example 1

Consider a monograph on a substance for human use where the Impurities section lists 8 impurities (A-H), 2 of which are indicated to be other detectable impurities (G, H) and there are the following acceptance criteria:

- *impurity A*: not more than the area of the principal peak in the chromatogram obtained with reference solution (b) (0.5 per cent),
- *any other impurity*: not more than the area of the principal peak in the chromatogram obtained with reference solution (c) (0.2 per cent),
- *total*: not more than twice the area of the principal peak in the chromatogram obtained with reference solution (b) (1.0 per cent),
- *disregard limit*: 0.25 times the area of the principal peak in the chromatogram obtained with reference solution (c) (0.05 per cent).

A substance complies with the test if:

- impurity A is present at a nominal concentration less than or equal to 0.5 per cent,
- impurities B, C, D, E, F are each present at a nominal concentration less than or equal to 0.2 per cent,
- any other impurity is present at a nominal concentration less than or equal to the identification threshold applicable for the active substance,
- the sum of nominal concentrations of impurities that are above the disregard limit is less than or equal to 1.0 per cent.

Example 2

Consider a monograph on a substance for human use where the Impurities section lists 6 impurities (A-F) with the following acceptance criteria.

In the chromatogram obtained with the test solution: the area of any peak, apart from the principal peak, is not greater than the area of the principal peak in the chromatogram obtained with reference solution (b) (0.5 per cent); the sum of the areas of all peaks, apart from the principal peak, is not greater than twice the area of the principal peak in the chromatogram obtained with reference solution (b) (1.0 per

cent). Disregard any peak obtained with the blank and any peak with an area less than 0.1 times the area of the principal peak in the chromatogram obtained with reference solution (b).

A substance complies with the test if:

- impurities A, B, C, D, E, F are each present at a nominal concentration less than or equal to 0.5 per cent,
- any other impurity is present at a nominal concentration less than or equal to the identification threshold applicable for the active substance,
- the sum of nominal concentrations of impurities that are above the disregard limit is less than or equal to 1.0 per cent.

Example 3

Consider a monograph on a substance for human use (for which the maximum daily dose is not more than 2 g/day) in more explicit style where the Impurities section lists 7 impurities, 6 of which (A-F) are defined as *Specified impurities* and the seventh (G) is given under *Other detectable impurities*.

Limits:

- *correction factor*: for the calculation of content, multiply the peak area of impurity A by 2.3,
- *impurity B*: not more than 3 times the area of the principal peak in the chromatogram obtained with reference solution (a) (0.3 per cent),
- *impurity E*: not more than 4 times the area of the principal peak in the chromatogram obtained with reference solution (a) (0.4 per cent),
- *impurities A, C, D, F*: for each impurity, not more than twice the area of the principal peak in the chromatogram obtained with reference solution (a) (0.2 per cent),
- *any other impurity*: for each impurity, not more than the area of the principal peak in the chromatogram obtained with reference solution (a) (0.1 per cent),
- *total*: not more than the area of the principal peak in the chromatogram obtained with reference solution (b) (1.0 per cent),
- *disregard limit*: 0.5 times the area of the principal peak in the chromatogram obtained with reference solution (a) (0.05 per cent).

A substance complies with the test if:

- impurity B is present at a nominal concentration less than or equal to 0.3 per cent,
- impurity E is present at a nominal concentration less than or equal to 0.4 per cent,
- impurities A, C, D, F are each present at a nominal concentration less than or equal to 0.2 per cent; the peak area of impurity A has been multiplied by 2.3 for the calculation of content,
- any other impurity is present at a nominal concentration less than or equal to 0.10 per cent (identification threshold),
- the sum of nominal concentrations of impurities that are above the disregard limit is less than or equal to 1.0 per cent.

Recommendations to users of monographs of active substances

Monographs give a specification for suitable quality of substances with impurity profiles corresponding to those taken into account during elaboration and/or revision of the monograph. It is the responsibility of the user of the substance to check that the monograph provides adequate control of impurities for a substance for pharmaceutical use from a given source, notably by using the procedure

for certification of suitability of the monographs of the European Pharmacopoeia.

A monograph with a related substances test based on a quantitative method (such as liquid chromatography, gas chromatography and capillary electrophoresis) provides adequate control of impurities for a substance from a given source if impurities present in amounts above the applicable identification threshold are specified impurities mentioned in the Impurities section.

If the substance contains impurities other than those mentioned in the Impurities section, it has to be verified that these impurities are detectable by the method described in the monograph, otherwise a new method must be developed and revision of the monograph must be requested. Depending on the contents found and the limits proposed, the identification and/or the qualification of these impurities must be considered.

Where a single related substances test covers different impurity profiles, only impurities for the known profile from a single source need to be reported in the certificate of analysis unless the marketing authorisation holder uses active substances with different impurity profiles.

Identification of impurities (peak assignment)

Where a monograph has an individual limit for an impurity, it is often necessary to define means of identification, for example using a reference substance, a representative chromatogram or relative retention. The user of the substance may find it necessary to identify impurities other than those for which the monograph provides a means of identification, for example to check the suitability of the specification for a given impurity profile by comparison with the Impurities section. The European Pharmacopoeia does not provide reference substances, representative chromatograms or information on relative retentions for this purpose, unless prescribed in the monograph. Users will therefore have to apply the available scientific techniques for identification.

New impurities/Specified impurities above the specified limit

Where a new manufacturing process or change in an established process leads to the occurrence of a new impurity, it is necessary to apply the provisions of the general monograph on *Substances for pharmaceutical use (2034)* regarding identification and qualification and to verify the suitability of the monograph for control of the impurity. A certificate of suitability is a means for confirming for a substance from a given source that the new impurity is adequately controlled or the certificate contains a method for control with a defined acceptance criterion. In the latter case revision of the monograph will be initiated.

Where a new manufacturing process or change in an established process leads to the occurrence of a specified impurity above the specified limit, it is necessary to apply the provisions of the general monograph on *Substances for pharmaceutical use (2034)* regarding qualification.

Chromatographic methods

General chapter 2.2.46. *Chromatographic separation techniques* deals with various aspects of impurities control.

Information is available via the EDQM web site (www.pheur.org) on commercial names for columns and other reagents and equipment found suitable during monograph development, where this is considered useful.

GLOSSARY

Disregard limit: in chromatographic tests, the nominal content at or below which peaks/signals are not taken into account for calculating a sum of impurities. The numerical values for the disregard limit and the reporting threshold are usually the same.

Identification threshold: a limit above which an impurity is to be identified.

Identified impurity: an impurity for which structural characterisation has been achieved.

Impurity: any component of a substance for pharmaceutical use that is not the chemical entity defined as the substance.

Nominal concentration: concentration calculated on the basis of the concentration of the prescribed reference and taking account of the prescribed correction factor.

Other detectable impurities: potential impurities with a defined structure that are known to be detected by the tests in a monograph but not known to be normally present above the identification threshold in substances used in medicinal products that have been authorised by the competent authorities of Parties to the Convention. They are unspecified impurities and are thus limited by a general acceptance criterion.

Potential impurity: an impurity that theoretically can arise during manufacture or storage. It may or may not actually appear in the substance. Where a potential impurity is known to be detected by the tests in a monograph but not known to be normally present in substances used in medicinal products that have been authorised by the competent authorities of Parties to the Convention, it will be included in the Impurities section under *Other detectable impurities* for information.

Qualification: the process of acquiring and evaluating data that establishes the biological safety of an individual impurity or a given impurity profile at the level(s) specified.

Qualification threshold: a limit above which an impurity is to be qualified.

Related substances: title used in monographs for general tests for organic impurities.

Reporting threshold: a limit above which an impurity is to be reported. Synonym: reporting level.

Specified impurity: an impurity that is individually listed and limited with a specific acceptance criterion in a monograph. A specified impurity can be either identified or unidentified.

Unidentified impurity: an impurity for which a structural characterisation has not been achieved and that is defined solely by qualitative analytical properties (for example, relative retention).

Unspecified impurity: an impurity that is limited by a general acceptance criterion and not individually listed with its own specific acceptance criterion.

01/2005:51100

5.11. CHARACTERS SECTION IN MONOGRAPHS

The General Notices indicate that the statements included in the Characters section are not to be interpreted in a strict sense and are not requirements. For information of users, the methods recommended to authors of monographs as the basis for statements concerning hygroscopicity, crystallinity and solubility are given below.

HYGROSCOPICITY

This method is to be carried out on a substance that complies with the test for loss on drying or water content of the monograph. The method gives an indication of the degree of hygroscopicity rather than a true determination.

Use a glass weighing vessel 50 mm in external diameter and 15 mm high. Weigh the vessel and stopper (m_1). Place the amount of substance prescribed for the test for loss on drying or water in the vessel and weigh (m_2). Place the unstoppered vessel in a desiccator at 25 °C containing a saturated solution of ammonium chloride or ammonium sulphate or place it in a climatic cabinet set at 25 ± 1 °C and 80 ± 2 per cent relative humidity. Allow to stand for 24 h. Stopper the weighing vessel and weigh (m_3).

Calculate the percentage increase in mass using the expression:

$$\frac{m_3 - m_2}{m_2 - m_1} \times 100$$

The result is interpreted as follows:

- *deliquescent*: sufficient water is absorbed to form a liquid,
- *very hygroscopic*: increase in mass is equal to or greater than 15 per cent,
- *hygroscopic*: increase in mass is less than 15 per cent and equal to or greater than 2 per cent,
- *slightly hygroscopic*: increase in mass is less than 2 per cent and equal to or greater than 0.2 per cent.

CRYSTALLINITY

This method is employed to establish the crystalline or amorphous nature of a substance.

Mount a few particles of the substance to be examined in mineral oil on a clean glass slide. Examine under a polarising microscope. Crystalline particles exhibit birefringence and extinction positions when the microscope stage is revolved.

SOLUBILITY

For this test a maximum of 111 mg of substance (for each solvent) and a maximum of 30 ml of each solvent are necessary.

Dissolving procedure

Shake vigorously for 1 min and place in a constant temperature device, maintained at a temperature of 25.0 ± 0.5 °C for 15 min. If the substance is not completely dissolved, repeat the shaking for 1 min and place the tube in the constant temperature device for 15 min.

Method

Weigh 100 mg of finely powdered substance (90) in a stoppered tube (16 mm in internal diameter and 160 mm long), add 0.1 ml of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *very soluble*.

If the substance is not completely dissolved, add 0.9 ml of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *freely soluble*.

If the substance is not completely dissolved, add 2.0 ml of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *soluble*.

If the substance is not completely dissolved, add 7.0 ml of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *sparingly soluble*.

If the substance is not completely dissolved, weigh 10 mg of finely powdered substance (90) in a stoppered tube, add 10.0 ml of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *slightly soluble*.

If the substance is not completely dissolved, weigh 1 mg of finely powdered substance (90) in a stoppered tube, add 10.0 ml of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *very slightly soluble*.

01/2005:1063

ALLERGEN PRODUCTS

Producta allergenica

DEFINITION

Allergen products are pharmaceutical preparations derived from extracts of naturally occurring source materials containing allergens, which are substances that cause or provoke allergic (hypersensitivity) disease. The allergenic components are most often of a proteinaceous nature.

Allergen products are intended for *in vivo* diagnosis or treatment of allergic (hypersensitivity) diseases attributed to these allergens.

Allergen products are available as finished products, as bulk preparations in dried form, solutions or suspensions intended to be further concentrated or diluted prior to use or as final preparations in solutions, suspensions or freeze-dried. Allergen products intended for parenteral, bronchial and conjunctival administration are sterile.

For *diagnostic use*, allergen products are usually prepared as unmodified extracts in a 50 per cent V/V solution of glycerol for skin-prick testing. For intradermal diagnosis or for provocation tests by nasal, ocular or bronchial routes, suitable dilutions of allergen products may be prepared by dilution of aqueous or glycerinated extracts, or by reconstitution immediately before use of unmodified freeze-dried extracts.

For *immunotherapy*, allergen products may be either unmodified extracts or extracts modified chemically and/or by adsorption onto different carriers (for example, aluminium hydroxide, calcium phosphate or tyrosine).

This monograph does not apply: to chemicals that are used solely for diagnosis of contact dermatitis; to chemically synthesised products; to allergens derived by rDNA technology; to finished products used on a named-patient basis. It does not necessarily apply to allergen products for veterinary use.

PRODUCTION

Allergen products are derived from a wide range of allergenic source materials. They are often prepared as bulk products intended to be further diluted or concentrated prior to use. They may be treated to modify or reduce the allergenic activity or remain unmodified.

SOURCE MATERIALS

Source materials for the preparation of allergen products are mostly pollens, moulds, mites, animal epithelia, hymenoptera venoms and certain foods.

They are described by their origin, nature, method of collection or production and pretreatment, and are stored under defined conditions which minimise deterioration.

The collection or production, as well as the handling of the source materials are such that uniform qualitative and quantitative composition is ensured as far as possible from batch to batch.

Pollens. Potential chemical contaminants, such as pesticides and heavy metals, must be minimised. Pollens contain not more than 1 per cent of foreign pollens as determined by microscopic examination. Pollens contain not more than 1 per cent of mould spores as determined by microscopic examination.

Mites and moulds. Biologically active contaminants such as mycotoxins in moulds must be minimised and any presence justified. Care must be taken to minimise any allergenic constituents of the media used for the cultivation of mites

and moulds as source materials. Culture media that contain substances of human or animal origin must be justified and, when required must be suitably treated to ensure the inactivation or elimination of possible transmissible agents of disease.

Animal epithelia. Animal epithelia must be obtained from healthy animals selected to avoid possible transmissible agents of disease.

MANUFACTURING PROCESS

Allergen products are generally obtained by extraction, and may be purified, from the source materials using appropriate methods shown to preserve the biological properties of the allergenic components. Allergen products are manufactured under conditions designed to minimise microbial growth and enzymatic degradation.

A purification procedure, if any, is designed to minimise the content of any potential irritant low-molecular-mass components or other non-allergenic components.

Allergen products may contain a suitable antimicrobial preservative. The nature and the concentration of the antimicrobial preservative have to be justified.

The manufacturing process comprises various stages.

Native allergen extracts result after separation from the extracted source materials.

Intermediate allergen products are obtained by further processing or modification of the native allergen extracts. The modification may be achieved by chemical processes (chemical conjugation) or physical processes (physical adsorption onto different carriers, for example, aluminium hydroxide, calcium phosphate or tyrosine). They may also be modified by inclusion into such vehicles as liposomes or microspheres, or by the addition of other biologically active agents to enhance efficacy or safety. Intermediate allergen products may be freeze-dried.

Bulk allergen preparations consist of products in solution or suspension which will not be further processed or modified, and are ready for dilution or filling into final containers.

IN-HOUSE REFERENCE PREPARATION

An appropriate representative preparation is selected as the In-House Reference Preparation (IHRP), characterised and used to verify batch-to-batch consistency. The IHRP is stored in suitably sized aliquots under conditions ensuring its stability, usually freeze-dried.

Characterisation of the In-House Reference Preparation.

The extent of characterisation of the IHRP depends on the nature of the allergenic source material, knowledge of the allergenic components and availability of suitable reagents, as well as the intended use. The characterised IHRP is used as reference in the batch control of native allergen extracts or intermediate allergen products and, if possible, in the batch control of final allergen preparations.

The In-House Reference Preparation (IHRP) is characterised by the protein content determination and a protein profile using relevant methods (such as isoelectric focusing, polyacrylamide gel electrophoresis, immunoelectrophoresis or molecular-mass profiling). Allergenic components may be detected by appropriate methods (for example immunoblotting or crossed radio-immunoelectrophoresis). Characterisation of the allergenic components may include identification of relevant allergens based on serological or others techniques using a pool or individual sera from allergic patients, or allergen-specific polyclonal or monoclonal antibodies. When allergen reference substances are available determination of the content of individual allergens may be performed. Individual allergens are identified according to internationally established nomenclature whenever possible.

Where possible, the biological potency of the IHRP is established by *in vivo* techniques such as skin testing, and expressed in units of biological activity. If not, for certain extracts, potency may be established by suitable immunoassays (for example, those based on the inhibition of the binding capacity of specific immunoglobulin E antibodies) or by quantitative techniques for a single major component.

IDENTIFICATION

Identity is confirmed at the intermediate or other applicable stage by comparison with the IHRP using protein profiling by appropriate methods (for example, isoelectric focusing, sodium dodecyl sulphate-polyacrylamide gel electrophoresis or immunoelectrophoresis).

TESTS

Various biochemical and immunological tests have been developed in order to characterise allergens qualitatively and quantitatively. However, some of the methods, particularly for the determination of allergenic activity and allergen profile, are not applicable to all products at present. This is because knowledge of the allergenic components or the required reagents is not available. Accordingly, allergen products have been classified in different categories with increasing test requirements, according to quality and intended use.

Where possible the following tests are applied to the final preparations. If not, they must be performed on the extracts as late as possible in the manufacturing process, for example, at the stage immediately prior to that stage (modification, dilution etc.) which renders the test not feasible on the final preparation.

Water (2.5.12). Not more than 5 per cent for freeze-dried products.

Sterility (2.6.1). Allergen products intended for parenteral, bronchial and conjunctival administration comply with the test for sterility.

Protein content: 80 per cent to 120 per cent of the stated content of a given batch. If the biological potency can be determined then the test for protein content may be omitted.

Protein profile. The protein composition determined by suitable methods corresponds to that of the IHRP.

Abnormal toxicity (2.6.9). Allergen products obtained from moulds and intended for parenteral administration (except skin-prick tests) comply with the test for abnormal toxicity for immunosera and vaccines for human use.

Various additional tests, somewith increasing selectivity, depending on the allergen product concerned can be applied, but in any case for allergen products intended for therapeutic use a validated test measuring the potency (total allergenic activity, determination of individual allergens or any other justified tests) must be applied.

Aluminium (2.5.13). Not less than 80 per cent and not more than 120 per cent of the stated amount but in any case not more than 1.25 mg per human dose unless otherwise justified and authorised, when aluminium hydroxide or aluminium phosphate is used as adsorbent.

Calcium (2.5.14). Not less than 80 per cent and not more than 120 per cent of the stated amount when calcium phosphate is used as adsorbent.

Antigen profile. The antigens are identified by means of suitable techniques using antigen-specific animal antibodies.

Allergen profile. Relevant allergenic components are identified by means of suitable techniques using allergen-specific human antibodies.

Total allergenic activity. The activity is 50 per cent to 200 per cent of the stated amount as assayed by inhibition of the binding capacity of specific immunoglobulin E antibodies or a suitable equivalent *in vitro* method.

Individual allergens: 50 per cent to 200 per cent of the stated amount, determined by a suitable method.

STORAGE

Adsorbed allergen products should not be frozen.

LABELLING

The label states:

- the biological potency and/or the protein content and/or the extraction concentration;
- the route of administration and the intended use;
- the storage conditions;
- where applicable, the name and amount of added antimicrobial preservative;
- for freeze-dried preparations:
 - the name, composition and volume of the reconstituting liquid to be added
 - the period of time within which the preparation is to be used after reconstitution;
- where applicable, that the preparation is sterile;
- where applicable the name and amount of adsorbent.

01/2005:0765

EXTRACTS

Extracta

DEFINITION

Extracts are preparations of liquid (liquid extracts and tinctures), semi-solid (soft extracts) or solid (dry extracts) consistency, obtained from herbal drugs or animal matters, which are usually in a dry state.

Different types of extract may be distinguished. Standardised extracts are adjusted within an acceptable tolerance to a given content of constituents with known therapeutic activity; standardisation is achieved by adjustment of the extract with inert material or by blending batches of extracts. Quantified extracts are adjusted to a defined range of constituents; adjustments are made by blending batches of extracts. Other extracts are essentially defined by their production process (state of the herbal drug or animal matter to be extracted, solvent, extraction conditions) and their specifications.

PRODUCTION

Extracts are prepared by suitable methods using ethanol or other suitable solvents. Different batches of the herbal drug or animal matter may be blended prior to extraction. The herbal drug or animal matter to be extracted may undergo a preliminary treatment, for example, inactivation of enzymes, grinding or defatting. In addition, unwanted matter may be removed after extraction.

Herbal drugs, animal matters and organic solvents used for the preparation of extracts comply with any relevant monograph of the Pharmacopoeia. For soft and dry extracts where the organic solvent is removed by evaporation, recovered or recycled solvent may be used, provided that the recovery procedures are controlled and monitored to ensure that solvents meet appropriate standards before re-use or admixture with other approved materials. Water used for the preparation of extracts is of suitable quality. Except for the test for bacterial endotoxins, water complying with

the section on Purified water in bulk of the monograph on *Purified water (0008)* is suitable. Potable water may be suitable if it complies with a defined specification that allows the consistent production of a suitable extract.

Where applicable, concentration to the intended consistency is carried out using suitable methods, usually under reduced pressure, and at a temperature at which deterioration of the constituents is reduced to a minimum. Essential oils that have been separated during processing may be restored to the extracts at an appropriate stage in the manufacturing process. Suitable excipients may be added at the various stages of the manufacturing process for example to improve technological qualities such as homogeneity or consistency. Suitable stabilisers and antimicrobial preservatives may also be added.

Extraction with a given solvent leads to typical proportions of characterised constituents in the extractable matter; during production of standardised and quantified extracts, purification procedures may be applied that increase these proportions with respect to the expected values; such extracts are referred to as “refined”.

IDENTIFICATION

Extracts are identified using a suitable method.

TESTS

Where applicable, as a result of analysis of the herbal drug or animal matter used for production and in view of the production process, tests for microbiological quality (5.1.4), heavy metals, aflatoxins, pesticide residues (2.8.13) in the extracts may be necessary.

ASSAY

Wherever possible, extracts are assayed by a suitable method.

LABELLING

The label states:

- the herbal drug or animal matter used,
- whether the extract is liquid, soft or dry, or whether it is a tincture,
- for standardised extracts, the content of constituents with known therapeutic activity,
- for quantified extracts, the content of constituents (markers) used for quantification,
- the ratio of the starting material to the genuine extract (DER),
- the solvent or solvents used for extraction,
- where applicable, that a fresh herbal drug or fresh animal matter has been used,
- where applicable, that the extract is “refined”,
- the name and amount of any excipient used including stabilisers and antimicrobial preservatives,
- where applicable, the percentage of dry residue.

Liquid extracts – extracta fluida

DEFINITION

Liquid extracts are liquid preparations of which, in general, 1 part by mass or volume is equivalent to 1 part by mass of the dried herbal drug or animal matter. These preparations are adjusted, if necessary, so that they satisfy the requirements for content of solvent, and, where applicable, for constituents.

PRODUCTION

Liquid extracts are prepared by using ethanol of suitable concentration or water to extract the herbal drug or animal matter, or by dissolving a soft or dry extract (which has been

produced using the same strength of extraction solvent as is used in preparing the liquid extract by direct extraction) of the herbal drug or animal matter in either ethanol of suitable concentration or water. Liquid extracts may be filtered, if necessary.

A slight sediment may form on standing, which is acceptable as long as the composition of the liquid extract is not changed significantly.

TESTS

Relative density (2.2.5). Where applicable, the liquid extract complies with the limits prescribed in the monograph.

Ethanol (2.9.10). For alcoholic liquid extracts, carry out the determination of ethanol content. The ethanol content complies with that prescribed.

Methanol and 2-propanol (2.9.11): maximum 0.05 per cent V/V of methanol and maximum 0.05 per cent V/V of 2-propanol for alcoholic liquid extracts unless otherwise prescribed.

Dry residue (2.8.16). Where applicable, the liquid extract complies with the limits prescribed in the monograph, corrected if necessary, taking into account any excipient used.

STORAGE

Protected from light.

LABELLING

The label states in addition to the requirements listed above:

- where applicable, the ethanol content in per cent V/V in the final extract.

Tinctures – tincturae

DEFINITION

Tinctures are liquid preparations which are usually obtained using either 1 part of herbal drug or animal matter and 10 parts of extraction solvent or 1 part of herbal drug or animal matter and 5 parts of extraction solvent.

PRODUCTION

Tinctures are prepared by maceration or percolation (outline methodology is given below) using only ethanol of a suitable concentration for extraction of the herbal drug or animal matter, or by dissolving a soft or dry extract (which has been produced using the same strength of extraction solvent as is used in preparing the tincture by direct extraction) of the herbal drug or animal matter in ethanol of a suitable concentration. Tinctures are filtered, if necessary.

Tinctures are usually clear. A slight sediment may form on standing which is acceptable as long as the composition of the tincture is not changed significantly.

Production by maceration. Unless otherwise prescribed, reduce the herbal drug or animal matter to be extracted to pieces of suitable size, mix thoroughly with the prescribed extraction solvent and allow to stand in a closed container for an appropriate time. The residue is separated from the extraction solvent and, if necessary, pressed out. In the latter case, the 2 liquids obtained are combined.

Production by percolation. If necessary, reduce the herbal drug or animal matter to be extracted to pieces of suitable size. Mix thoroughly with a portion of the prescribed extraction solvent and allow to stand for an appropriate time. Transfer to a percolator and allow the percolate to flow at room temperature slowly making sure that the herbal drug

or animal matter to be extracted is always covered with the remaining extraction solvent. The residue may be pressed out and the expressed liquid combined with the percolate.

01/2005:1434

TESTS

Relative density (2.2.5). Where applicable, the tincture complies with the limits prescribed in the monograph.

Ethanol (2.9.10). The ethanol content complies with that prescribed.

Methanol and 2-propanol (2.9.11): maximum 0.05 per cent V/V of methanol and maximum 0.05 per cent V/V of 2-propanol, unless otherwise prescribed.

Dry residue (2.8.16). Where applicable, the tincture complies with the limits prescribed in the monograph, corrected if necessary, taking into account any excipient used.

STORAGE

Protected from light.

LABELLING

The label states in addition to the requirements listed above:

- for tinctures other than standardised and quantified tinctures, the ratio of starting material to extraction liquid or of starting material to final tincture,
- the ethanol content in per cent V/V in the final tincture.

Soft extracts – *extracta spissa*

DEFINITION

Soft extracts are semi-solid preparations obtained by evaporation or partial evaporation of the solvent used for extraction.

TESTS

Dry residue (2.8.16). The soft extract complies with the limits prescribed in the monograph.

Solvents. Where applicable, a monograph on a soft extract prescribes a limit test for the solvent used for extraction.

STORAGE

Protected from light.

Dry extracts – *extracta sicca*

DEFINITION

Dry extracts are solid preparations obtained by evaporation of the solvent used for their production. Dry extracts usually have a loss on drying or a water content of not greater than 5 per cent *m/m*.

TESTS

Water (2.2.13). Where applicable, the dry extract complies with the limits prescribed in the monograph.

Loss on drying (2.8.17). Where applicable, the dry extract complies with the limits prescribed in the monograph.

Solvents. Where applicable, a monograph on a dry extract prescribes a limit test for the solvent used for extraction.

STORAGE

In an airtight container, protected from light.

HERBAL DRUG PREPARATIONS

Plantae medicinales praeparatore

DEFINITION

Herbal drug preparations are obtained by subjecting herbal drugs to treatments such as extraction, distillation, expression, fractionation, purification, concentration or fermentation. These include comminuted or powdered herbal drugs, tinctures, extracts, essential oils, expressed juices and processed exudates.

Herbal teas comply with the monograph on *Herbal teas* (1435).

Instant herbal teas consist of powder or granules of one or more herbal drug preparation(s) intended for the preparation of an oral solution immediately before use.

01/2005:1433

HERBAL DRUGS

Plantae medicinales

DEFINITION

Herbal drugs are mainly whole, fragmented or cut, plants, parts of plants, algae, fungi, lichen in an unprocessed state, usually in dried form but sometimes fresh. Certain exudates that have not been subjected to a specific treatment are also considered to be herbal drugs. Herbal drugs are precisely defined by the botanical scientific name according to the binominal system (genus, species, variety and author).

PRODUCTION

Herbal drugs are obtained from cultivated or wild plants. Suitable collection, cultivation, harvesting, drying, fragmentation and storage conditions are essential to guarantee the quality of herbal drugs.

Herbal drugs are, as far as possible, free from impurities such as soil, dust, dirt and other contaminants such as fungal, insect and other animal contaminations. They are not rotten. If a decontaminating treatment has been used, it is necessary to demonstrate that the constituents of the plant are not affected and that no harmful residues remain. The use of ethylene oxide is prohibited for the decontamination of herbal drugs.

IDENTIFICATION

Herbal drugs are identified using their macroscopic and microscopic descriptions and any further tests that may be required (for example, thin-layer chromatography).

TESTS

A test for foreign matter (2.8.2) is carried out, unless otherwise prescribed in the individual monographs.

A specific appropriate test may apply to herbal drugs liable to be falsified.

If appropriate, the herbal drugs comply with other tests, for example, total ash (2.4.16), ash insoluble in hydrochloric acid (2.8.1), extractable matter, swelling index (2.8.4) and bitterness value.

The test for loss on drying (2.2.32) is carried out on herbal drugs, unless otherwise prescribed in the individual monographs. A determination of water (2.2.13) is carried out for herbal drugs with a high essential oil content.

Herbal drugs comply with the requirements for pesticide residues (2.8.13). The requirements take into account the nature of the plant, where necessary the preparation in which the plant might be used, and where available the knowledge of the complete record of treatment of the batch of the plant. The content of pesticide residues may be determined by the method described in the annex to the general method.

The risk of contamination of herbal drugs by heavy metals must be considered. If an individual monograph does not prescribe limits for heavy metals or specific elements such limits may be required if justified.

Recommendations on the microbiological quality of products consisting solely of one or more herbal drugs are given in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4. – Category 4).

Where necessary limits for aflatoxins may be required.

In some specific circumstances, the risk of radioactive contamination is to be considered.

ASSAY

Unless otherwise justified and authorised herbal drugs are assayed by an appropriate method.

STORAGE

Store protected from light.

01/2005:1435

HERBAL TEAS

Plantae ad ptisanam

DEFINITION

Herbal teas consist exclusively of one or more herbal drugs intended for oral aqueous preparations by means of decoction, infusion or maceration. The preparation is prepared immediately before use.

Herbal teas are usually supplied in bulk form or in sachets.

The herbal drugs used comply with the appropriate individual European Pharmacopoeia monographs or in their absence to the general monograph on *Herbal drugs* (1433).

Recommendations on the microbiological quality of herbal teas (5.1.4. – Category 4) take into account the prescribed preparation method (use of boiling or non-boiling water).

IDENTIFICATION

The identity of herbal drugs present in herbal teas is checked by botanical examinations.

TESTS

The proportion of herbal drugs present in herbal teas is checked by appropriate methods.

Herbal teas in sachets comply with the following test:

Uniformity of mass. Determine the average mass of twenty randomly chosen units as follows: weigh a single full sachet of herbal tea, open it without losing any fragments. Empty it completely using a brush. Weigh the empty sachet and calculate the mass of the contents by subtraction. Repeat the operation on the nineteen remaining sachets. Unless otherwise justified not more than two of the twenty individual masses of the contents deviate from the average

mass of the contents by more than the percentage deviation shown in the table below and none deviates by more than twice that percentage.

Average mass	Percentage deviation
less than 1.5 g	15 per cent
1.5 g to 2.0 g included	10 per cent
more than 2.0 g	7.5 per cent

STORAGE

Store protected from light.

01/2005:0084

IMMUNOSERA FOR HUMAN USE, ANIMAL

Immunosera ex animale ad usum humanum

DEFINITION

Animal immunosera for human use are liquid or freeze-dried preparations containing purified immunoglobulins or immunoglobulin fragments obtained from serum or plasma of immunised animals of different species.

The immunoglobulins or immunoglobulin fragments have the power of specifically neutralising or binding to the antigen used for immunisation. The antigens include microbial or other toxins, human antigens, suspensions of bacterial and viral antigens and venoms of snakes, scorpions and spiders. The preparation is intended for intravenous or intramuscular administration, after dilution where applicable.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently immunosera of acceptable safety, potency in man and stability.

Any reagent of biological origin used in the production of immunosera shall be free of contamination with bacteria, fungi and viruses. The method of preparation includes a step or steps that have been shown to remove or inactivate known agents of infection.

Methods used for production are validated, effective, reproducible and do not impair biological activity of the product.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

Reference preparation. A batch shown to be suitable in clinical trials, or a batch representative thereof, is used as the reference preparation for the tests for high molecular mass proteins and purity.

ANIMALS

The animals used are of a species approved by the competent authority, are healthy and exclusively reserved for production of immunoserum. They are tested and shown to be free from a defined list of infectious agents. The introduction of animals into a closed herd follows specified procedures, including definition of quarantine measures. Where appropriate, additional specific agents are considered depending on the geographical localisation of the establishment used for the breeding and production of the animals. The feed originates from a controlled source and no animal proteins are added. The suppliers of animals are certified by the competent authority.

If the animals are treated with antibiotics, a suitable withdrawal period is allowed before collection of blood or plasma. The animals are not treated with penicillin antibiotics. If a live vaccine is administered, a suitable waiting period is imposed between vaccination and collection of serum or plasma for immunoserum production.

IMMUNISATION

The antigens used are identified and characterised, where appropriate; where relevant, they are shown to be free from extraneous infectious agents. They are identified by their names and a batch number; information on the source and preparation are recorded.

The selected animals are isolated for at least 1 week before being immunised according to a defined schedule with booster injections at suitable intervals. Adjuvants may be used.

Animals are kept under general health surveillance and specific antibody production is controlled at each cycle of immunisation.

Animals are thoroughly examined before collection of blood or plasma. If an animal shows any pathological lesion not related to the immunisation process, it is not used, nor are any other of the animals in the group concerned, unless it is evident that their use will not impair the safety of the product.

COLLECTION OF BLOOD OR PLASMA

Collection of blood is made by venepuncture or plasmapheresis. The puncture area is shaved, cleaned and disinfected. The animals may be anaesthetised under conditions that do not influence the quality of the product. Unless otherwise prescribed, an antimicrobial preservative may be added. The blood or plasma is collected in such a manner as to maintain sterility of the product. The blood or plasma collection is conducted at a site separate from the area where the animals are kept or bred and the area where the immunoserum is purified. If the serum or plasma is stored before further processing, precautions are taken to avoid microbial contamination.

Several single plasma or serum samples may be pooled before purification. The single or pooled samples are tested before purification for the following tests.

Tests for contaminating viruses. If an antimicrobial preservative is added, it must be neutralised before carrying out the tests or the tests carried out on a sample taken before addition of the antimicrobial preservative. Each pool is tested for contaminating viruses by suitable *in vitro* tests.

Each pool is tested for viruses by inoculation to cell cultures capable of detecting a wide range of viruses relevant for the particular product.

Potency. Carry out a biological assay as indicated in the monograph and express the result in International Units per millilitre, where applicable. A validated *in vitro* method may also be used.

Protein content. Dilute the product to be examined with a 9 g/l solution of *sodium chloride R* to obtain a solution containing about 15 mg of protein in 2 ml. To 2 ml of this solution in a round-bottomed centrifuge tube add 2 ml of a 75 g/l solution of *sodium molybdate R* and 2 ml of a mixture of 1 volume of *nitrogen-free sulphuric acid R* and 30 volumes of *water R*. Shake, centrifuge for 5 min, decant the supernatant liquid and allow the inverted tube to drain on filter paper. Determine the nitrogen in the residue by the method of sulphuric acid digestion (2.5.9) and calculate the content of protein by multiplying by 6.25. The protein content is within approved limits.

PURIFICATION AND VIRAL INACTIVATION

The immunoglobulins are concentrated and purified by fractional precipitation, chromatography, immunoabsorption or by other chemical or physical methods. They may be processed further by enzyme treatment. The methods are selected and validated to avoid contamination at all steps of processing and to avoid formation of protein aggregates that effect immunobiological characteristics of the product. For products intended to consist of immunoglobulin fragments, the methods are validated to guarantee total fragmentation. The methods of purification used are such that they do not generate additional components that compromise the quality and the safety of the product.

Unless otherwise justified and authorised, validated procedures are applied for removal and/or inactivation of viruses. The procedures are selected to avoid the formation of polymers or aggregates and, unless the product is intended to consist of Fab' fragments, to minimise the splitting of F(ab')₂ into Fab' fragments.

After purification and treatment for removal and/or inactivation of viruses, a stabiliser may be added to the intermediate product, which may be stored for a period defined in the light of stability data.

Only an intermediate product that complies with the following requirements may be used in the preparation of the final bulk.

Purity. Examine by non-reducing polyacrylamide gel electrophoresis (2.2.31), by comparison with the reference preparation, the bands are compared in intensity and no additional bands are found.

FINAL BULK

The final bulk is prepared from a single intermediate product or from a pool of intermediate products obtained from animals of the same species. Intermediate products with different specificities may be pooled.

An antimicrobial preservative and a stabiliser may be added. If an antimicrobial preservative has been added to the blood or plasma, the same substance is used as antimicrobial preservative in the final bulk.

Only a final bulk that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable physico-chemical method. It contains not less than 85 per cent and not more than 115 per cent of the amount stated on the label.

Sterility (2.6.1). It complies with the test for sterility.

FINAL LOT

The final bulk of immunoserum is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that complies with the requirements prescribed below under Identification, Tests and Assay may be released for use. Provided that the tests for osmolality, protein content, molecular-size distribution, antimicrobial preservative, stabiliser, purity, foreign proteins and albumin and the assay have been carried out with satisfactory results on the final bulk, they may be omitted on the final lot.

Reconstitute the preparation to be examined as stated on the label immediately before carrying out the identification, tests (except those for solubility and water) and assay.

IDENTIFICATION

The identity is established by immunological tests and, where necessary, by determination of biological activity. The assay may also serve for identification.

CHARACTERS

Immunosera are clear to opalescent and colourless to very faintly yellow liquids. They are free from turbidity. Freeze-dried products are white or slightly yellow powders or solid friable masses. After reconstitution they show the same characteristics as liquid preparations.

TESTS

Solubility. To a container of the preparation to be examined, add the volume of the liquid for reconstitution stated on the label. The preparation dissolves completely within the time stated on the label.

Extractable volume (2.9.17). It complies with the requirement for extractable volume.

pH (2.2.3). The pH is within the limits approved for the particular product.

Osmolality (2.2.35): minimum 240 mosmol/kg after dilution, where applicable.

Protein content: 90 per cent to 110 per cent of the amount stated on the label, and not more than 100 g/l.

Dilute the preparation to be examined with a 9 g/l solution of *sodium chloride R* to obtain a solution containing about 15 mg of protein in 2 ml. To 2 ml of this solution in a round-bottomed centrifuge tube add 2 ml of 75 g/l solution of *sodium molybdate R* and 2 ml of a mixture of 1 volume of *nitrogen-free sulphuric acid R* and 30 volumes of *water R*. Shake, centrifuge for 5 min, decant the supernatant liquid and allow the inverted tube to drain on filter paper. Determine the nitrogen in the residue by the method of sulphuric acid digestion (2.5.9) and calculate the content of protein by multiplying by 6.25.

Molecular-size distribution. Examine by liquid chromatography (2.2.29 or 2.2.30). It complies with the specification approved for the particular product.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable physicochemical method. The amount is not less than the minimum amount shown to be effective and is not greater than 115 per cent of that stated on the label.

Phenol (2.5.15): maximum 2.5 g/l for preparations containing phenol.

Stabiliser. Determine the amount of stabiliser by a suitable physico-chemical method. The preparation contains not less than 80 per cent and not more than 120 per cent of the quantity stated on the label.

Purity. Examine by non-reducing polyacrylamide gel electrophoresis (2.2.31), by comparison with the reference preparation. No additional bands are found for the preparation to be examined.

Foreign proteins. When examined by precipitation tests with specific antisera, only protein from the declared animals species is shown to be present, unless otherwise prescribed, for example where material of human origin is used during production.

Albumin. Unless otherwise prescribed in the monograph, when examined electrophoretically, the content of albumin is not greater than the limit approved for the particular product and, in any case, not greater than 3 per cent.

Water (2.5.12): maximum 3 per cent.

Sterility (2.6.1). It complies with the test for sterility.

Pyrogens (2.6.8). Unless otherwise justified and authorised, it complies with the test for pyrogens. Unless otherwise prescribed, inject 1 ml per kilogram of the rabbit's body mass.

ASSAY

Carry out a biological assay as indicated in the monograph and express the result in International Units per millilitre, where appropriate. A validated *in vitro* method may also be used.

STORAGE

Store protected from light at the temperature stated on the label. Do not allow liquid preparations to freeze.

Expiry date. The expiry date is calculated from the beginning of the assay.

LABELLING

The label states:

- the number of International Units per millilitre, where applicable,
- the amount of protein per container,
- for freeze-dried preparations,
 - the name and volume of the reconstituting liquid to be added,
 - that the immunoserum is to be used immediately after reconstitution,
 - the time required for complete dissolution,
- the route of administration,
- the storage conditions,
- the expiry date, except for containers of less than 1 ml which are individually packed. The expiry date may be omitted from the label on the container, provided it is shown on the package and the label on the package states that the container must be kept in the package until required for use,
- the animal species of origin,
- the name and amount of any antimicrobial preservative, any stabiliser and any other substance added to the immunoserum.

IMMUNOSERA FOR VETERINARY USE

Immunosera ad usum veterinarium

DEFINITION

Immunosera for veterinary use are preparations containing immunoglobulins which have the power of specifically neutralising the toxins formed by or of specifically combining with the antigen used for their preparation. They may be crude or purified.

PRODUCTION

Immunosera are obtained from the serum of healthy animals immunised by injections of toxins or toxoids, venins of snakes, viruses, suspensions of micro-organisms or other suitable antigens. If a penicillin is used during immunisation, animals must not be bled until 8 days after the last administration. One or more suitable antimicrobial preservatives may be added and are invariably added if the preparations are issued in multidose containers.

For purified immunosera, the globulins containing the immune substances may be obtained from the crude immunoserum by enzyme treatment and fractional precipitation or by other chemical or physical methods. Purified immunosera are most stable at about pH 6.

CHARACTERS

Immunosera are liquids that vary in colour according to the method of preparation. They are distributed aseptically in sterile containers which are then closed. When they are freeze-dried they consist of crusts or powders that are soluble in water.

TESTS

The following requirements refer to liquid immunosera and reconstituted freeze-dried immunosera.

pH (2.2.3). The pH of crude immunosera is 7.0 to 8.0. The pH of purified immunosera is 6.0 to 7.0.

Foreign proteins. When examined by precipitation with specific antisera, immunosera are shown to consist exclusively of proteins of the animal species used for the preparation.

Albumins. Purified immunosera comply with the test for albumins. Unless otherwise prescribed in the monograph, when examined electrophoretically, purified immunosera show not more than a trace of albumin.

Total protein Not more than 170 g/l. Carry out the determination of nitrogen by sulphuric acid digestion (2.5.9) and multiply the result by 6.25.

Phenol (2.5.15). When the immunoserum contains phenol, the concentration is not more than 5 g/l.

Sterility (2.6.1). Immunosera comply with the test for sterility. When the volume of liquid in a container is greater than 100 ml, the method of membrane filtration is used wherever possible. If this method is used, incubate the media for not less than 14 days. Where the method of membrane filtration cannot be used, the method of direct inoculation may be used.

Where the volume of liquid in each container is 20 ml or more, the minimum volume to be used for each culture medium is 10 per cent of the contents or 5 ml whichever is less.

The appropriate number of items to be tested (2.6.1) is 1 per cent of the batch with a minimum of 4 and a maximum of 10.

POTENCY

Carry out the biological assay prescribed in the monograph and express the result in International Units per millilitre when such exist.

STORAGE

Store protected from light at a temperature of 5 ± 3 °C. Liquid immunosera should not be allowed to freeze.

Expiry date. The expiry date is calculated from the beginning of the test for Potency. It applies to immunosera stored in the prescribed conditions.

LABELLING

The label states:

- the name of the preparation,
- "for veterinary use",
- the number of International Units per millilitre, where such exist,
- the batch number or other reference,
- the storage conditions,
- the expiry date,
- the animal species for which the immunoserum is intended,
- the name of the animal species of origin,
- the name and amount of any antimicrobial preservative or other substance added to the immunoserum,

- whether any substance is likely to cause an adverse reaction,
- any contra-indications to the use of the product,
- for freeze-dried immunosera:
 - the name or composition and the volume of the reconstituting liquid to be added,
 - that the immunoserum should be used immediately after reconstitution,
- the doses recommended for different species,
- the name and address of the manufacturer.

01/2005:1468

PRODUCTS OF FERMENTATION

Producta ab fermentatione

This monograph applies to indirect gene products obtained by fermentation. It is not applicable to:

- *monographs in the Pharmacopoeia concerning vaccines for human or veterinary use;*
- *products derived from continuous cell lines of human or animal origin;*
- *direct gene products that result from the transcription and translation from nucleic acid to protein, whether or not subject to post-translational modification;*
- *products obtained by semi-synthesis from a product of fermentation and those obtained by biocatalytic transformation;*
- *whole broth concentrates or raw fermentation products.*

This monograph provides general requirements for the development and manufacture of products of fermentation. These requirements are not necessarily comprehensive in a given case and requirements complementary or additional to those prescribed in this monograph may be imposed in an individual monograph or by the competent authority.

DEFINITION

For the purposes of this monograph, products of fermentation are active or inactive pharmaceutical substances produced by controlled fermentation as indirect gene products. They are primary or secondary metabolites of micro-organisms such as bacteria, yeasts, fungi and micro-algae, whether or not modified by traditional procedures or recombinant DNA (rDNA) technology. Such metabolites include vitamins, amino acids, antibiotics, alkaloids and polysaccharides. They may be obtained by batch or continuous fermentation processes followed by procedures such as extraction, concentration, purification and isolation.

PRODUCTION

Production is based on a process that has been validated and shown to be suitable. The extent of validation depends on the critical nature of the respective process step.

CHARACTERISATION OF THE PRODUCER MICRO-ORGANISM

The history of the micro-organism used for production is documented. The micro-organism is adequately characterised. This may include determination of the phenotype of the micro-organism, macroscopic and microscopic methods and biochemical tests and, if appropriate, determination of the genotype of the micro-organism and molecular genetic tests.

PROCESSES USING A SEED-LOT SYSTEM

The *master cell bank* is a homogeneous suspension or lyophilisate of the original cells distributed into individual containers for storage. The viability and productivity of the cells under the selected storage conditions and their suitability for initiating a satisfactory production process after storage must be demonstrated.

Propagation of the master cell bank may take place through a seed-lot system that uses a working cell bank.

The *working cell bank* is a homogeneous suspension or lyophilisate of the cell material derived from the master cell bank, distributed in equal volumes into individual containers for storage (for example, in liquid nitrogen).

Production may take place by batch or continuous culture and may be terminated under defined conditions.

All containers in a cell bank are stored under identical conditions. Once removed from storage, the individual ampoules, vials or culture straws are not returned to the cell bank.

PROCESSES USING STAGED GROWTH IN CULTURES

The contents of a container of the working cell bank are used, if necessary after resuspension, to prepare an inoculum in a suitable medium. After a suitable period of growth, the cultures are used to initiate the fermentation process, if necessary following preculture in a fermentor. The conditions to be used at each stage of the process are defined and must be met with each production run.

CHANGE CONTROL

If the production process is altered in a way that causes a significant change in the impurity profile of the product, the critical steps associated with this change in impurity profile are revalidated.

If a significant change has taken place in the micro-organism used for production that causes a significant change in the impurity profile of the product, the critical steps of the production process associated with this change, particularly the procedure for purification and isolation, are revalidated.

Revalidation includes demonstration that new impurities present in the product as a result of the change are adequately controlled by the test procedures. If necessary, additional or alternative tests must be introduced with appropriate limits. If the change in the process or in the micro-organism results in an increase in the level of an impurity already present, the acceptability of such an increase is addressed.

When a master cell bank is replaced, the critical steps of the production process must be revalidated to the extent necessary to demonstrate that no adverse change has occurred in the quality and safety of the product. Particular attention must be given to possible changes in the impurity profile of the product if a modified or new micro-organism is introduced into the process.

RAW MATERIALS

The raw materials employed in the fermentation and/or down-stream processing are of suitable quality for the intended purpose. They are tested to ensure that they comply with written specifications.

Levels of bioburden in media or in the inlet air for aeration are reduced to an adequately low level to ensure that if microbiological contamination occurs, it does not adversely affect the quality, purity and safety of the product. Addition of components such as nutrients, precursors, and substrates during fermentation takes place aseptically.

IN-PROCESS CONTROLS

In-process controls are in place to ensure the consistency of the conditions during fermentation and down-stream processing and of the quality of the isolated product. Particular attention must be paid to ensure that any microbial contamination that adversely affects the quality, purity and safety of the product is detected by the controls applied.

Production conditions may be monitored, as appropriate, by suitable procedures for example to control and check:

- temperature,
- pH,
- rate of aeration,
- rate of agitation,
- pressure,

and to monitor the concentration of the required product.

DOWN-STREAM PROCESSING

At the end of fermentation, the producer micro-organism is inactivated or removed. Further processing is designed to reduce residues originating from the culture medium to an acceptable level and to ensure that the desired product is recovered with consistent quality.

Various purification processes may be used, for example, charcoal treatment, ultrafiltration and solvent extraction. It must be demonstrated that the process or processes chosen reduce to a minimum or remove:

- residues from the producer micro-organism, culture media, substrates and precursors,
- unwanted transformation products of substrates and precursors.

If necessary, suitable tests are performed either as in-process controls or on the isolated product of fermentation.

IDENTIFICATION, TESTS AND ASSAY

The requirements with which the product must comply throughout its period of validity, as well as specific test methods, are stated in the individual monographs.

STORAGE

See the individual monographs.

LABELLING

See the individual monographs.

PRODUCTS WITH RISK OF TRANSMITTING AGENTS OF ANIMAL SPONGIFORM ENCEPHALOPATHIES

Producta cum possibili transmissione
vectorium encephalopathiarum
spongiformium animalium

DEFINITION

Products with risk of transmitting agents of animal spongiform encephalopathies are those derived from tissues or secretions of animals susceptible to transmissible spongiform encephalopathies other than by experimental challenge. This monograph applies to all substances or preparations obtained from such animals and to all substances or preparations where products obtained from

such animals are included as active substances or excipients or have been used during production, for example as raw or source materials, starting materials or reagents.

PRODUCTION

Production complies with chapter *Minimising the risk of transmitting animal spongiform encephalopathy agents via medicinal products* (5.2.8).

01/2005:0125

RADIOPHARMACEUTICAL PREPARATIONS

Radiopharmaceutica

DEFINITION

For the purposes of this general monograph, radiopharmaceutical preparations cover:

- radiopharmaceutical: any medicinal product which, when ready for use, contains one or more radionuclides (radioactive isotopes) included for a medicinal purpose,
- radionuclide generator: any system incorporating a fixed parent radionuclide from which is produced a daughter radionuclide which is to be removed by elution or by any other method and used in a radiopharmaceutical preparation,
- kit for radiopharmaceutical preparation: any preparation to be reconstituted and/or combined with radionuclides in the final radiopharmaceutical preparation, usually prior to its administration,
- radiopharmaceutical precursor: any other radionuclide produced for the radio-labelling of another substance prior to administration.

A nuclide is a species of atom characterised by the number of protons and neutrons in its nucleus (and hence by its atomic number Z , and mass number A) and also by its nuclear energy state. Isotopes of an element are nuclides with the same atomic number but different mass numbers. Nuclides containing an unstable arrangement of protons and neutrons will transform spontaneously to either a stable or another unstable combination of protons and neutrons with a constant statistical probability. Such nuclides are said to be radioactive and are called radionuclides. The initial unstable nuclide is referred to as the parent radionuclide and the resulting nuclide as the daughter nuclide.

The radioactive decay or transformation may involve the emission of charged particles, electron capture (EC) or isomeric transition (IT). The charged particles emitted from the nucleus may be alpha particles (helium nucleus of mass number 4) or beta particles (negatively charged, generally called electrons or positively charged, generally called positrons). The emission of charged particles from the nucleus may be accompanied by the emission of gamma rays. Gamma rays are also emitted in the process of isomeric transition. These emissions of gamma rays may be partly replaced by the ejection of electrons known as internal conversion electrons. This phenomenon, like the process of electron capture, causes a secondary emission of X-rays (due to the reorganisation of the electrons in the atom). This secondary emission may itself be partly replaced by the ejection of electrons known as Auger electrons. Radionuclides with a deficit of neutrons may decay by emitting positrons. These radionuclides are called positron emitters. Positrons are annihilated on contact with electrons,

the process being accompanied by the emission of usually two gamma photons, each with an energy of 511 keV, generally emitted at 180° to each other, termed annihilation radiation.

The decay of a radionuclide is governed by the laws of probability with a characteristic decay constant and follows an exponential law. The time in which a given quantity of a radionuclide decays to half its initial value is termed the half-life ($T_{1/2}$).

The penetrating power of each radiation varies considerably according to its nature and its energy. Alpha particles are completely absorbed in a thickness of a few micrometers to some tens of micrometers of matter. Beta particles are completely absorbed in a thickness of several millimetres to several centimetres of matter. Gamma rays are not completely absorbed but only attenuated and a tenfold reduction may require, for example, several centimetres of lead. For most absorbents, the denser the absorbent, the shorter the range of alpha and beta particles and the greater the attenuation of gamma rays.

Each radionuclide is characterised by an invariable half-life, expressed in units of time and by the nature and energy of its radiation or radiations. The energy is expressed in electronvolts (eV), kilo-electronvolts (keV) or mega-electronvolts (MeV).

Generally the term "radioactivity" is used to describe the phenomenon of radioactive decay and to express the physical quantity (activity) of this phenomenon. The radioactivity of a preparation is the number of nuclear disintegrations or transformations per unit time.

In the International System (SI), radioactivity is expressed in becquerel (Bq) which is one nuclear transformation per second. Absolute radioactivity measurements require a specialised laboratory but identification and measurement of radiation can be carried out relatively by comparing with standardised preparations provided by laboratories recognised by the competent authority.

Radionuclidic purity: the ratio, expressed as a percentage, of the radioactivity of the radionuclide concerned to the total radioactivity of the radiopharmaceutical preparation. The relevant radionuclidic impurities are listed with their limits in the individual monographs.

Radiochemical purity: the ratio, expressed as a percentage, of the radioactivity of the radionuclide concerned which is present in the radiopharmaceutical preparation in the stated chemical form, to the total radioactivity of that radionuclide present in the radiopharmaceutical preparation. The relevant radiochemical impurities are listed with their limits in the individual monographs.

Chemical purity: in monographs on radiopharmaceutical preparations chemical purity is controlled by specifying limits on chemical impurities.

Isotopic carrier: a stable isotope of the element concerned either present or added to the radioactive preparation in the same chemical form as that in which the radionuclide is present.

Specific radioactivity: the radioactivity of a radionuclide per unit mass of the element or of the chemical form concerned.

Radioactive concentration: the radioactivity of a radionuclide per unit volume.

Total radioactivity: the radioactivity of the radionuclide, expressed per unit (vial, capsule, ampoule, generator, etc).

Starting materials: all the constituents which make up the radiopharmaceutical preparations.

Period of validity: the time during which specifications described in the monograph must be fulfilled. Expiry date and, if necessary, time must be clearly stated.

PRODUCTION

A radiopharmaceutical preparation monograph describes as precisely as possible the method of production of the radionuclide. A radiopharmaceutical preparation contains its radionuclide:

- as an element in atomic or molecular form, e.g. [^{133}Xe], [^{15}O] O_2 ,
- as an ion, e.g. [^{131}I]iodide, [$^{99\text{m}}\text{Tc}$]pertechnetate,
- included in or attached to organic molecules by chelation, e.g. [^{111}In]oxine or by covalent bonding, e.g. 2- ^{18}F fluoro-2-deoxy-D-glucose.

The practical ways of producing radionuclides for use in, or as radiopharmaceutical preparations are:

- neutron bombardment of target materials (generally in nuclear reactors),
- charged particles bombardment of target materials (in accelerators such as cyclotrons),
- nuclear fission of heavy nuclides of target materials (generally after neutron or particle bombardment),
- from a radionuclide generator.

NEUTRON OR CHARGED PARTICLE BOMBARDMENT

The nuclear reaction and the probability of its occurrence in unit time are dependent on the nature and physical properties of the target material and the nature, energy and quantity of the incident particles.

The nuclear transformation occurring through particle bombardment may be written in the form:

target nucleus (bombarding particle, emitted particle or radiation) produced nucleus.

In addition to the desired nuclear reaction adventitious transformations may occur. These will be influenced by the energy of the incident particle and the purity of the target material. Such adventitious transformations may give rise to radionuclidic impurities.

NUCLEAR FISSION

A small number of nuclides with a high atomic number are fissionable and the most frequently used reaction is the fission of uranium-235 by neutrons in a nuclear reactor. Iodine-131, molybdenum-99 and xenon-133 may be produced by nuclear fission of uranium-235. Their extraction from a mixture of more than 200 other radionuclides must be carefully controlled in order to minimise the radionuclidic impurities.

RADIONUCLIDE GENERATORS

Radionuclide generator systems use a relatively long-lived parent radionuclide which decays to a daughter radionuclide, usually with a shorter half-life.

By separating the daughter radionuclide from the parent radionuclide by a chemical or physical process, it is possible to use the daughter at a considerable distance from the production site of the generators despite its short half-life.

TARGET MATERIALS

The isotopic composition and purity of the target material will determine the relative percentages of the principal radionuclide and radionuclidic impurities. The use of isotopically enriched target material in which the abundance

of the required target nuclide has been artificially increased, can improve the production yield and the purity of the desired radionuclide.

The chemical form, the purity, the physical state and the chemical additives, as well as the bombardment conditions and the direct physical and chemical environment will determine the chemical state and chemical purity of the radionuclides which are produced.

In the production of radionuclides and particularly of short-lived radionuclides it may not be possible to determine any of these quality criteria before further processing and manufacture of radiopharmaceutical preparations. Therefore each batch of target material must be tested in test production runs before its use in routine radionuclide production and manufacture of the radiopharmaceutical preparations, to ensure that under specified conditions, the target yields the radionuclide in the desired quantity and quality specified.

The target material is contained in a holder in gaseous, liquid or solid state, in order to be irradiated by a beam of particles. For neutron bombardment, the target material is commonly contained in quartz ampoules or high purity aluminium or titanium containers. It is necessary to ascertain that no interaction can occur between the container and its contents under the irradiation conditions (temperature, pressure, time).

For charged particle bombardment, the holder for target material is usually built of aluminium or another appropriate metal, with inlet and outlet ports, a surrounding cooling system and usually a thin metal foil target window. The nature and thickness of the target window have a particular influence on the yield of the nuclear reaction and may also affect the radionuclidic purity.

The production procedure clearly describes:

- target material,
- construction of the holder for target material,
- loading of target material into the irradiation system,
- method of irradiation (bombardment),
- separation of the desired radionuclide,

and evaluates all effects on the efficiency of the production in terms of quality and quantity of the produced radionuclide.

The chemical state of the isolated radionuclide may play a major role in all further processing.

PRECURSORS FOR SYNTHESIS

Generally, these precursors are not produced on a large scale. Some precursors are synthesised by the radiopharmaceutical production laboratory, others are supplied by specialised producers or laboratories.

Tests for identity, for chemical purity and the assay must be performed by validated procedures.

When batches of precursors are accepted using data from the certificates of analysis, suitable evidence has to be established to demonstrate the consistent reliability of the supplier's analyses and at least one identity test must be conducted. It is recommended to test precursor materials in production runs before their use for the manufacture of radiopharmaceutical preparations, to ensure that under specified production conditions, the precursor yields the radiopharmaceutical preparation in the desired quantity and quality specified.

PERFORMANCE OF THE PRODUCTION SYSTEM

All operations, from the preparation of the target to the dispensing of the final radiopharmaceutical preparation, must be clearly documented including their impact on the purity of the final product and the efficiency of the procedure.

Where possible, in-process controls are performed and the results recorded at each production step to identify at which level a possible discrepancy from the normal production pathway may have occurred.

a) The production of radiopharmaceutical preparations may make use of mechanical and automated processes that are used in the pharmaceutical industry, subject to adapting these to the specificity of the radioactive starting material and to the requirements of radioprotection.

b) For radiopharmaceutical preparations containing shortlived radionuclides, such as certain positron emitters, remotely controlled production and automated radiosynthesis are generally used. For radionuclides with a very short half-life (less than 20 min) the control of the performance of the production system is an important measure to assure the quality of the radiopharmaceutical preparation before its release.

c) Any production procedure must be validated in test production runs before its use in routine manufacture of radiopharmaceutical preparations, to ensure that under specified production conditions, the production system yields the radiopharmaceutical preparation in the desired quantity and specified quality.

d) The preparation of the dosage form of the final radiopharmaceutical preparation in the practice of nuclear medicine generally involves limited radioactivity starting from ready-to-use radiopharmaceutical preparations, generators, kits and radioactive precursors. All conditions which may affect the quality of the product (e.g. radiochemical purity and sterility) must be clearly defined and must include appropriate measures for radiation protection.

IDENTIFICATION

Radioactive decay: radioactivity decays at an exponential rate with a decay constant characteristic of each radionuclide.

The curve of exponential decay (decay curve) is described by the equation:

$$A_t = A_0 e^{-\lambda t}$$

A_t = the radioactivity at time t ,

A_0 = the radioactivity at time $t = 0$,

λ = the decay constant characteristic of each radionuclide,

e = the base of Napierian logarithms.

The half-life ($T_{1/2}$) is related to the decay constant (λ) by the equation:

$$T_{1/2} = \frac{\ln 2}{\lambda} \quad (\ln 2 \approx 0.693)$$

The radionuclide is generally identified by its half-life or by the nature and energy of its radiation or radiations or by both, as prescribed in the monograph.

Measurement of half-life. The half-life is measured with a suitable detection apparatus such as an ionisation chamber, a Geiger-Müller counter, a scintillation counter (solid crystal, liquid) or a semiconductor detector. The preparation to be tested is used as such or diluted or dried in a capsule after appropriate dilution. The radioactivity chosen, having regard to experimental conditions, must be of a sufficiently high level to allow detection during several estimated half-lives, but not too high to minimise count rate losses, for example due to dead time.

The radioactive source is prepared in a manner that will avoid loss of material during handling. If it is a liquid

(solution), it is contained in bottles or sealed tubes. If it is a solid (residue from drying in a capsule), it is protected by a cover consisting of a sheet of adhesive cellulose acetate or of some other material.

The same source is measured in the same geometrical conditions and at intervals usually corresponding to half of the estimated half-life throughout a time equal to about three half-lives. The correct functioning of the apparatus is checked using a source of long half-life and, if necessary, corrections for any changes of the count rate have to be applied (see Measurement of Radioactivity).

A graph can be drawn with time as the abscissa and the logarithm of the relative instrument reading (e.g. count rate) as the ordinate. The calculated half-life differs by not more than 5 per cent from the half-life stated in the Pharmacopoeia, unless otherwise stated.

Determination of the nature and energy of the radiation.

The nature and energy of the radiation emitted may be determined by several procedures including the construction of an attenuation curve and the use of spectrometry. The attenuation curve can be used for analysis of electron radiation; spectrometry is mostly used for identification of gamma rays and detectable X-rays.

The *attenuation curve* is drawn for pure electron emitters when no spectrometer for beta rays is available or for beta/gamma emitters when no spectrometer for gamma rays is available. This method of estimating the maximum energy of beta radiation gives only an approximate value. The source, suitably mounted to give constant geometrical conditions, is placed in front of the thin window of a Geiger-Müller counter or a proportional counter. The source is protected as described above. The count rate of the source is then measured. Between the source and the counter are placed, in succession, at least six aluminium screens of increasing mass per unit area within such limits that with a pure beta emitter this count rate is not affected by the addition of further screens. The screens are inserted in such a manner that constant geometrical conditions are maintained. A graph is drawn showing, as the abscissa, the mass per unit area of the screen expressed in milligrams per square centimetre and, as the ordinate, the logarithm of the count rate for each screen examined. A graph is drawn in the same manner for a standardised preparation. The mass attenuation coefficients are calculated from the median parts of the curves, which are practically rectilinear.

The *mass attenuation coefficient* μ_m , expressed in square centimetres per milligram, depends on the energy spectrum of the beta radiation and on the nature and the physical properties of the screen. It therefore allows beta emitters to be identified. It is calculated using the equation:

$$\mu_m = \frac{\ln A_1 - \ln A_2}{m_2 - m_1}$$

m_1 = mass per unit area of the lightest screen,

m_2 = mass per unit area of the heaviest screen, m_1 and m_2 being within the rectilinear part of the curve,

A_1 = count rate for mass per unit area m_1 ,

A_2 = count rate for mass per unit area m_2 .

The mass attenuation coefficient μ_m thus calculated does not differ by more than 10 per cent from the coefficient obtained under identical conditions using a standardised preparation of the same radionuclide.

The range of beta particles is a further parameter which can be used for the determination of the beta energy. It is obtained from the graph described above as the mass per unit

area corresponding to the intersection of the extrapolations of the descending rectilinear part of the attenuation curve and the horizontal line of background radioactivity.

Liquid scintillation counting may be used to obtain spectra of α and β^- emitters (see measurement of radioactivity).

Gamma spectrometry is used to identify radionuclides by the energy and intensity of their gamma rays and X-rays.

The preferred detector for gamma and X-ray spectrometry is a germanium semiconductor detector. A thallium-activated sodium iodide scintillation detector is also used but this has a much lower energy resolution.

The gamma detector has to be calibrated using standard sources because the detection efficiency is a function of the energy of the gamma and X-rays as well as the form of the source and the source-to-detector distance. The detection efficiency may be measured using a calibrated source of the radionuclide to be measured or, for more general work, a graph of efficiency against gamma and X-ray energy may be constructed from a series of calibrated sources of various radionuclides.

The gamma and X-ray spectrum of a radionuclide which emits gamma and X-rays is unique to that nuclide and is characterised by the energies and the number of photons of particular energies emitted per transformation from one energy level to another energy level. This property contributes to the identification of radionuclides present in a source and to their quantification. It allows the estimation of the degree of radionuclidic impurity by detecting peaks other than those expected.

It is possible to establish the rate of the decay of radioactivity using gamma spectrometry since the peaks diminish in amplitude as a function of the half-life. If, in such a source, a radioactive impurity with a different half-life is present, it is possible to detect the latter by identification of the characteristic peak or peaks whose amplitudes decrease at a different rate from that expected for the particular radionuclide. A determination of the half-life of the additional peaks by repeated measurements of the sample will help to identify the impurity.

The *Table of physical characteristics of radionuclides mentioned in the European Pharmacopoeia (5.7)* summarises the most commonly accepted physical characteristics of radionuclides used in preparations which are the subject of monographs in the European Pharmacopoeia. In addition, the Table states the physical characteristics of the main potential impurities of the radionuclides mentioned in the monographs.

By “transition probability” is meant the probability of the transformation of a nucleus in a given energy state, via the transition concerned. Instead of “probability” the terms “intensity” and “abundance” are frequently used.

By “emission probability” is meant the probability of an atom of a radionuclide giving rise to the emission of the particles or radiation concerned.

Irrespective of whether the one or the other meaning is intended, probability is usually measured in terms of 100 disintegrations.

MEASUREMENT OF RADIOACTIVITY

The radioactivity of a preparation is stated at a given date and, if necessary, time.

The absolute measurement of the radioactivity of a given sample may be carried out if the decay scheme of the radionuclide is known, but in practice many corrections are required to obtain accurate results. For this reason it

is common to carry out the measurement with the aid of a primary standard source. Primary standards may not be available for short-lived radionuclides e.g. positron emitters. Measuring instruments are calibrated using suitable standards for the particular radionuclides. Standards are available from the laboratories recognised by the competent authority. Ionisation chambers and Geiger-Müller counters may be used to measure beta and beta/gamma emitters; scintillation or semiconductor counters or ionisation chambers may be used for measuring gamma emitters; low-energy beta emitters require a liquid-scintillation counter. For the detection and measurement of alpha emitters, specialised equipment and techniques are required. For an accurate comparison of radioactive sources, it is essential for samples and standards to be measured under similar conditions.

Low-energy beta emitters may be measured by liquid-scintillation counting. The sample is dissolved in a solution containing one or more often two organic fluorescent substances (primary and secondary scintillators), which convert part of the energy of disintegration into photons of light, which are detected by a photomultiplier and converted into electrical impulses. When using a liquid-scintillation counter, comparative measurements are corrected for light-quenching effects. Direct measurements are made, wherever possible, under similar conditions, (e.g. volumes and type of solutions) for the source to be examined and the standard source.

All measurements of radioactivity must be corrected by subtracting the background due to radioactivity in the environment and to spurious signals generated in the equipment itself.

With some equipment, when measurements are made at high levels of radioactivity, it may be necessary to correct for loss by coincidence due to the finite resolving time of the detector and its associated electronic equipment. For a counting system with a fixed dead time τ following each count, the correction is:

$$N = \frac{N_{obs}}{1 - N_{obs}\tau}$$

N = the true count rate per second,

N_{obs} = the observed count rate per second,

τ = the dead time, in seconds.

With some equipment this correction is made automatically. Corrections for loss by coincidence must be made before the correction for background radiation.

If the time of an individual measurement, t_m is not negligible short compared with the half-life, $T_{1/2}$, the decay during this measurement time must be taken into account. After having corrected the instrument reading (count rate, ionisation current, etc.) for background and, if necessary, for losses due to electronic effects, the decay correction during measurement time is:

$$R_{corr} = \frac{R \frac{t_m \ln 2}{T_{1/2}}}{1 - \exp\left(-\frac{t_m \ln 2}{T_{1/2}}\right)}$$

R_{corr} = instrument reading corrected to the beginning of the individual measurement,

R = instrument reading before decay correction, but already corrected for background, etc.

The results of determinations of radioactivity show variations which derive mainly from the random nature of nuclear transformation. A sufficient number of counts must be registered in order to compensate for variations in the number of transformations per unit of time. The standard deviation is the square root of the counts, so at least 10 000 counts are necessary to obtain a relative standard deviation of not more than 1 per cent (confidence interval: 1 sigma).

All statements of radioactive content are accompanied by a statement of the date and, if necessary, the time at which the measurement was made. This statement of the radioactive content must be made with reference to a time zone (GMT, CET). The radioactivity at other times may be calculated from the exponential equation or from tables.

The radioactivity of a solution is expressed per unit volume to give the radioactive concentration.

RADIONUCLIDIC PURITY

In most of the cases, to state the radionuclidic purity of a radiopharmaceutical preparation, the identity of every radionuclide present and their radioactivity must be known. The most generally useful method for examination of radionuclidic purity is that of gamma spectrometry. It is not a completely reliable method because alpha- and beta-emitting impurities are not usually easily detectable and, when sodium iodide detectors are employed, the peaks due to gamma emitting impurities are often obscured by the spectrum of the principal radionuclide.

The individual monographs prescribe the radionuclidic purity required (for example, the gamma-ray spectrum does not significantly differ from that of a standardised preparation) and may set limits for specific radionuclidic impurities (for example, cobalt-60 in cobalt-57). While these requirements are necessary, they are not in themselves sufficient to ensure that the radionuclidic purity of a preparation is sufficient for human use. The manufacturer must examine the product in detail and especially must examine preparations of radionuclides of short half-life for impurities of long half-life after a suitable period of decay. In this way, information on the suitability of the manufacturing processes and the adequacy of the testing procedures may be obtained. In cases where two or more positron emitting radionuclides need to be identified and/or differentiated, as e.g. 18F-impurities in 13N-preparations, half-life determinations need to be carried out in addition to gamma spectrometry.

Due to differences in the half-lives of the different radionuclides present in a radiopharmaceutical preparation, the radionuclidic purity changes with time. The requirement of the radionuclidic purity must be fulfilled throughout the period of validity. It is sometimes difficult to carry out these tests before authorising the release for use of the batch when the half-life of the radionuclide in the preparation is short. The test then constitutes a control of the quality of production.

RADIOCHEMICAL PURITY

The determination of radiochemical purity requires separation of the different chemical substances containing the radionuclide and estimating the percentage of radioactivity associated with the declared chemical substance. Radiochemical impurities may originate from:

- radionuclide production,
- subsequent chemical procedures,
- incomplete preparative separation,
- chemical changes during storage.

The requirement of the radiochemical purity must be fulfilled throughout the period of validity.

In principle, any method of analytical separation may be used in the determination of radiochemical purity. For example, the monographs for radiopharmaceutical products may include paper chromatography (2.2.26), thin-layer chromatography (2.2.27), electrophoresis (2.2.37), size-exclusion chromatography (2.2.30), gas chromatography (2.2.28) and liquid chromatography (2.2.29). The technical description of these analytical methods is set out in the monographs. Moreover certain precautions special to radioactivity must also be taken for radiation protection.

In a hospital environment thin-layer and paper chromatography are mostly used. In paper and thin-layer chromatography, a volume equal to that described in the monograph is deposited on the starting-line as prescribed in the general methods for chromatography. It is preferable not to dilute the preparation to be examined but it is important to avoid depositing such a quantity of radioactivity that counting losses by coincidence occur during measurement of the radioactivity. On account of the very small quantities of the radioactive material applied, a carrier may be added when specified in a particular monograph. After development, the support is dried and the positions of the radioactive areas are detected by autoradiography or by measurement of radioactivity over the length of the chromatogram, using suitable collimated counters or by cutting the strips and counting each portion. The positions of the spots or areas permit chemical identification by comparison with solutions of the same chemical substances (non-radioactive) using a suitable detection method.

Radioactivity may be measured by integration using an automatic-plotting instrument or a digital counter. The ratios of the areas under the peaks give the ratios of the radioactive concentration of the chemical substances. When the strips are cut into portions, the ratios of the quantities of radioactivity measured give the ratio of concentrations of the radioactive chemical species.

SPECIFIC RADIOACTIVITY

Specific radioactivity is usually calculated taking into account the radioactive concentration (radioactivity per unit volume) and the concentration of the chemical substance being studied, after verification that the radioactivity is attributable only to the radionuclide (radionuclidic purity) and the chemical species (radiochemical purity) concerned.

Specific radioactivity changes with time. The statement of the specific radioactivity therefore includes reference to a date and, if necessary, time. The requirement of the specific radioactivity must be fulfilled throughout the period of validity.

CHEMICAL PURITY

The determination of chemical purity requires quantification of the individual chemical impurities specified in the monograph.

ENANTIOMERIC PURITY

Where appropriate, the stereoisomeric purity has to be verified.

PHYSIOLOGICAL DISTRIBUTION

A physiological distribution test is prescribed, if necessary, for certain radiopharmaceutical preparations. The distribution pattern of radioactivity observed in specified organs, tissues or other body compartments of an appropriate animal species (usually rats or mice) can be a reliable indication of the expected distribution in humans and thus of the suitability for the intended purpose.

The individual monograph prescribes the details concerning the performance of the test and the physiological distribution requirements which must be met for the radiopharmaceutical preparation. A physiological distribution conforming to the requirements will assure appropriate distribution of the radioactive compounds to the intended biological target in humans and limits its distribution to non-target areas.

In general, the test is performed as follows.

Each of three animals is injected intravenously with the preparation to be tested. If relevant, the species, sex, strain and weight and/or age of the animals is specified in the monograph. The test injection is the radiopharmaceutical preparation as it is intended for human use. Where applicable, products are reconstituted according to the manufacturer's instructions. In some cases, dilution immediately before injection may be necessary.

The administration will normally be made via the intravenous route for which purpose the caudal vein is used. Other veins such as the saphenous, femoral, jugular or penile veins may be used in special cases. Animals showing evidence of extravasation of the injection (observed at the time of injection or revealed by subsequent assay of tissue radioactivity) are rejected from the test.

Immediately after injection each animal is placed in a separate cage which will allow collection of excreta and prevent contamination of the body surface of the animal.

At the specified time after injection, the animals are killed by an appropriate method and dissected. Selected organs and tissues are assayed for their radioactivity using a suitable instrument as described elsewhere in this monograph. The physiological distribution is then calculated and expressed in terms of the percentage of the radioactivity which is found in each of the selected organs or tissues. For this purpose the radioactivity in an organ may be related to the injected radioactivity calculated from the radioactive content of the syringe measured before and after injection. For some radiopharmaceutical preparations it may be appropriate to determine the ratio of the radioactivity in weighed samples of selected tissues (radioactivity/mass).

For a preparation to meet the requirements of the test, the distribution of radioactivity in at least two of the three animals must comply with all the specified criteria.

STERILITY

Radiopharmaceutical preparations for parenteral administration must be prepared using precautions designed to exclude microbial contamination and to ensure sterility. The test for sterility is carried out as described in the general method for sterility (2.6.1). Special difficulties arise with radiopharmaceutical preparations because of the short half-life of some radionuclides, small size of batches and the radiation hazards. It is not always possible to await the results of the test for sterility before authorisation of the release for use of the batch concerned. Parametric release (5.1.1) of the product manufactured by a fully validated process is the method of choice in such cases. When aseptic manufacturing is used, the test for sterility has to be executed as a control of the quality of production.

When the size of a batch of the radiopharmaceutical preparation is limited to one or a few samples (e.g. therapeutic or very short-lived radiopharmaceutical preparation), sampling the batch for sterility testing may not be applicable. If the radiopharmaceutical preparation is sterilised by filtration and/or aseptically processed (5.1.1) process validation is critical.

When the half-life of the radionuclide is very short (e.g. less than 20 min), the administration of the radiopharmaceutical preparation to the patient is generally on-line with a validated production system.

For safety reasons (high level of radioactivity) it is not possible to use the quantity of the radiopharmaceutical preparations as required in the test for sterility (2.6.1). The method by membrane filtration is to be preferred to limit irradiation of personnel.

Notwithstanding the requirements concerning the use of antimicrobial preservatives in *Parenteral preparations (0520)*, their addition to radiopharmaceutical preparations in multidose containers is not obligatory, unless prescribed in the monograph.

BACTERIAL ENDOTOXINS - PYROGENS

For certain radiopharmaceutical preparations a test for bacterial endotoxins is prescribed. The test is carried out as described in the general method (2.6.14), taking the necessary precautions to limit irradiation of the personnel carrying out the test.

The limit for bacterial endotoxins is indicated in the individual monograph.

When the nature of the radiopharmaceutical preparation results in an interference by inhibition or activation and it is not possible to eliminate the interfering factor(s), the test for pyrogens (2.6.8) may be specifically prescribed.

It is sometimes difficult to carry out these tests before releasing the batch for use when the half-life of the radionuclide in the preparation is short. The test then constitutes a control of the quality of production.

STORAGE

Store in an airtight container in a place that is sufficiently shielded to protect personnel from irradiation by primary or secondary emissions and that complies with national and international regulations concerning the storage of radioactive substances. During storage, containers may darken due to irradiation. Such darkening does not necessarily involve deterioration of the preparations.

Radiopharmaceutical preparations are intended for use within a short time and the end of the period of validity must be clearly stated.

LABELLING

The labelling of radiopharmaceutical preparations complies with the relevant national and European legislation.

The label on the direct container states:

- the name of the preparation and/or its reference,
- the name of the manufacturer,
- an identification number,
- for liquid and gaseous preparations: the total radioactivity in the container, or the radioactive concentration per millilitre at a stated date and, if necessary, time, and the volume of liquid in the container,
- for solid preparations (such as freeze-dried preparations): the total radioactivity at a stated date and, if necessary, time. After reconstitution with the appropriate solution, the preparation is considered as a liquid preparation,
- for capsules: the radioactivity per capsule at a stated date and, if necessary, time and the number of capsules in the container.

The labelling can be adapted in certain cases (e.g. radiopharmaceutical preparations containing short-lived radionuclides).

In addition, the label on the outer package states:

- the route of administration,
- the period of validity or the expiry date,
- the name and concentration of any added antimicrobial preservative,
- where applicable, any special storage conditions.

01/2005:0784

RECOMBINANT DNA TECHNOLOGY, PRODUCTS OF

Producta ab ADN recombinante

This monograph provides general requirements for the development and manufacture of products of recombinant DNA technology. These requirements are not necessarily comprehensive in a given case and requirements complementary or additional to those prescribed in this monograph may be imposed in an individual monograph or by the competent authority.

The monograph is not applicable to modified live organisms that are intended to be used directly in man and animals, for example as live vaccines.

DEFINITION

Products of rDNA technology are produced by genetic modification in which DNA coding for the required product is introduced, usually by means of a plasmid or a viral vector, into a suitable micro-organism or cell line, in which that DNA is expressed and translated into protein. The desired product is then recovered by extraction and purification. The cell or micro-organism before harbouring the vector is referred to as the host cell, and the stable association of the two used in the manufacturing process is referred to as the host-vector system.

PRODUCTION

Production is based on a validated seed-lot system using a host-vector combination that has been shown to be suitable to the satisfaction of the competent authority. The seed-lot system uses a master cell bank and a working cell bank derived from the master seed lot of the host-vector combination. A detailed description of cultivation, extraction and purification steps and a definition of the production batch shall be established.

The determination of the suitability of the host-vector combination and the validation of the seed-lot system include the following elements.

CLONING AND EXPRESSION

The suitability of the host-vector system, particularly as regards microbiological purity, is demonstrated by:

Characterisation of the host cell, including source, phenotype and genotype, and of the cell-culture media.

Documentation of the strategy for the cloning of the gene and characterisation of the recombinant vector including:

- i. the origin and characterisation of the gene;
- ii. nucleotide-sequence analysis of the cloned gene and the flanking control regions of the expression vector. The cloned sequences are kept to a minimum and all relevant expressed sequences are clearly identified and confirmed at the RNA level.

The DNA sequence of the cloned gene is normally confirmed at the seed-lot stage, up to and beyond the normal level of population doubling for full-scale fermentation. In certain

systems, for example, where multiple copies of the gene are inserted into the genome of a continuous cell line, it may be inappropriate to sequence the cloned gene at the production level. Under these circumstances, Southern blot analysis of total cellular DNA or sequence analysis of the messenger RNA (m RNA) may be helpful, particular attention being paid to the characterisation of the expressed protein;

- iii. the construction, genetics and structure of the complete expression vector.

Characterisation of the host-vector system including:

- i. mechanism of transfer of the vector into the host cells;
- ii. copy number, physical state and stability of the vector inside the host cell;
- iii. measures used to promote and control the expression.

CELL-BANK SYSTEM

The master cell bank is a homogeneous suspension of the original cells already transformed by the expression vector containing the desired gene, distributed in equal volumes into individual containers for storage (for example, in liquid nitrogen). In some cases it may be necessary to establish separate master cell banks for the expression vector and the host cells.

The working cell bank is a homogeneous suspension of the cell material derived from the master cell bank(s) at a finite passage level, distributed in equal volumes into individual containers for storage (for example, in liquid nitrogen).

In both cell banks, all containers are treated identically during storage and, once removed from storage, the containers are not returned to the cell stock.

The cell bank may be used for production at a finite passage level or for continuous-culture production.

Production at a finite passage level

This cultivation method is defined by a limited number of passages or population doublings which must not be exceeded during production. The maximum number of cell doublings, or passage levels, during which the manufacturing process routinely meets the criteria described below must be stated.

Continuous-culture production

By this cultivation method the number of passages or population doublings is not restricted from the beginning of production. Criteria for the harvesting as well as for the termination of production have to be defined by the manufacturer. Monitoring is necessary throughout the life of the culture; the required frequency and type of monitoring will depend on the nature of the production system and the product.

Information is required on the molecular integrity of the gene being expressed and on the phenotypic and genotypic characteristics of the host cell after long-term cultivation. The acceptance of harvests for further processing must be clearly linked to the schedule of monitoring applied and a clear definition of a "batch" of product for further processing is required.

VALIDATION OF THE CELL BANKS

Validation of the cell banks includes:

- i. stability by measuring viability and the retention of the vector;
- ii. identity of the cells by phenotypic features;
- iii. where appropriate, evidence that the cell banks are free from potentially oncogenic or infective adventitious agents (viral, bacterial, fungal or mycoplasmal). Special attention has to be given to viruses that can commonly contaminate the species from which the cell line has been derived. Certain cell lines contain endogenous viruses, for example,

retroviruses, which may not readily be eliminated. The expression of these organisms, under a variety of conditions known to cause their induction, shall be tested for;

iv. for mammalian cells, details of the tumorigenic potential of the cell bank shall be obtained.

CONTROL OF THE CELLS

The origin, form, storage, use and stability at the anticipated rate of use must be documented in full for all cell banks under conditions of storage and recovery. New cell banks must be fully validated.

VALIDATION OF THE PRODUCTION PROCESS

Extraction and purification

The capacity of each step of the extraction and purification procedure to remove and/or inactivate contaminating substances derived from the host cell or culture medium, including, in particular, virus particles, proteins, nucleic acids and added substances, must be validated.

Validation studies are carried out to demonstrate that the production process routinely meets the following criteria:

- exclusion of extraneous agents from the product. Studies including, for example, viruses with relevant physico-chemical features are undertaken, and a reduction capacity for such contaminants at each relevant stage of purification is established;
- adequate removal of vector, host-cell, culture medium and reagent-derived contaminants from the product. The reduction capacity for DNA is established by spiking. The reduction of proteins of animal origin can be determined by immunochemical methods;
- maintenance within stated limits of the yield of product from the culture;
- adequate stability of any intermediate of production and/or manufacturing when it is intended to use intermediate storage during the process.

Characterisation of the substance

The identity, purity, potency and stability of the final bulk product are established initially by carrying out a wide range of chemical, physical, immunochemical and biological tests. Prior to release, each batch of the product is tested by the manufacturer for identity and purity and an appropriate assay is carried out.

Production consistency

Suitable tests for demonstrating the consistency of the production and purification are performed. The tests include, especially characterisation tests, in-process controls and final-product tests, for example:

AMINO-ACID COMPOSITION

Partial amino-acid sequence analysis. The sequence data permit confirmation of the correct *N*-terminal processing and detection of loss of the *C*-terminal amino acids.

Peptide mapping. Peptide mapping using chemical and/or enzymatic cleavage of the protein product and analysis by a suitable method such as two-dimensional gel electrophoresis, capillary electrophoresis or liquid chromatography must show no significant difference between the test protein and the reference preparation. Peptide mapping can also be used to demonstrate correct disulphide bonding.

DETERMINATION OF MOLECULAR MASS

Cloned-gene retention. The minimum amount in percentage of the cells containing the vector or the cloned gene after cultivation is approved by the relevant authority.

Total protein. The yield of protein is determined.

Chemical purity. The purity of the protein product is analysed in comparison with a reference preparation by a suitable method such as liquid chromatography, capillary electrophoresis or sodium dodecyl sulphate polyacrylamide gel electrophoresis.

Host-cell-derived proteins. Host-cell-derived proteins are detected by immunochemical methods, using, for example, polyclonal antisera raised against protein components of the host-vector system used to manufacture the product, unless otherwise prescribed. The following types of procedure may be used: liquid-phase displacement assays (for example, radio-immunoassay), liquid-phase direct-binding assays and direct-binding assays using antigens immobilised on nitrocellulose (or similar) membranes (for example, dot-immunoblot assays, Western blots). General requirements for the validation of immunoassay procedures are given under 2.7.1. *Immunochemical Methods*. In addition, immunoassay methods for host-cell contaminants meet the following criteria:

- *Antigen preparations.* Antisera are raised against a preparation of antigens derived from the host organism, into which has been inserted the vector used in the manufacturing process that lacks the specific gene coding for the product. This host cell is cultured, and proteins are extracted, using conditions identical to those used for culture and extraction in the manufacturing process. Partly purified preparations of antigens, using some of the purification steps in the manufacturing process, may also be used for the preparation of antisera.
- *Calibration and standardisation.* Quantitative data are obtained by comparison with dose-response curves obtained using standard preparations of host-derived protein antigens. Since these preparations are mixtures of poorly defined proteins, a standard preparation is prepared and calibrated by a suitable protein determination method. This preparation is stored in a stable state suitable for use over an extended period of time.
- *Antisera.* Antisera contain high-avidity antibodies recognising as many different proteins in the antigen mixture as possible, and do not cross-react with the product.

Host-cell- and vector-derived DNA. Residual DNA is detected by hybridisation analysis, using suitably sensitive, sequence-independent analytical techniques or other suitably sensitive analytical techniques.

Hybridisation analysis

DNA in the test sample is denatured to give single-stranded DNA, immobilised on a nitrocellulose or other suitable filter and hybridised with labelled DNA prepared from the host-vector manufacturing system (DNA probes). Although a wide variety of experimental approaches is available, hybridisation methods for measurement of host-vector DNA meet the following criteria:

- *DNA probes.* Purified DNA is obtained from the host-vector system grown under the same conditions as those used in the manufacturing process. Host chromosomal DNA and vector DNA may be separately prepared and used as probes.
- *Calibration and standardisation.* Quantitative data are obtained by comparison with responses obtained using standard preparations. Chromosomal DNA probes and vector DNA probes are used with chromosomal DNA and vector DNA standards, respectively. Standard preparations are calibrated by spectroscopic measurements and stored in a state suitable for use over an extended period of time.

- *Hybridisation conditions.* The stringency of hybridisation conditions is such as to ensure specific hybridisation between probes and standard DNA preparations and the drug substances must not interfere with hybridisation at the concentrations used.

Sequence-independent techniques

Suitable procedures include: detection of sulphonated cytosine residues in single-stranded DNA (where DNA is immobilised on a filter and cytosines are derivatised *in situ*, before detection and quantitation using an antibody directed against the sulphonated group); detection of single-stranded DNA using a fragment of single-stranded DNA bound to a protein and an antibody of this protein. Neither procedure requires the use of specific host or vector DNA as an assay standard. However, the method used must be validated to ensure parallelism with the DNA standard used, linearity of response and non-interference of either the drug substance or excipients of the formulation at the dilutions used in the assay.

IDENTIFICATION, TESTS AND ASSAY

The requirements with which the final product (bulk material or dose form) must comply throughout its period of validity, as well as specific test methods, are stated in the individual monograph.

STORAGE

See the individual monographs.

LABELLING

See the individual monographs.

Polymorphism. Individual monographs do not usually specify crystalline or amorphous forms, unless bioavailability is affected. All forms of a substance for pharmaceutical use comply with the requirements of the monograph, unless otherwise indicated.

PRODUCTION

Substances for pharmaceutical use are manufactured by procedures that are designed to ensure a consistent quality and comply with the requirements of the individual monograph or approved specification.

The provisions of general chapter 5.10 apply to the control of impurities in substances for pharmaceutical use.

Whether or not it is specifically stated in the individual monograph that the substance for pharmaceutical use:

- is a recombinant protein or another substance obtained as a direct gene product based on genetic modification, where applicable, the substance also complies with the requirements of the general monograph on *Products of recombinant DNA technology (0784)*;
- is obtained from animals susceptible to transmissible spongiform encephalopathies other than by experimental challenge, where applicable, the substance also complies with the requirements of the general monograph on *Products with risk of transmitting agents of animal spongiform encephalopathies (1483)*;
- is a substance derived from a fermentation process whether or not the micro-organisms involved are modified by traditional procedures or recombinant DNA (rDNA) technology, where applicable, the substance complies with the requirements of the general monograph on *Products of fermentation (1468)*.

If solvents are used during production, they are of suitable quality. In addition, their toxicity and their residual level are taken into consideration (5.4). If water is used during production, it is of suitable quality.

If substances are produced or processed to yield a certain form or grade, that specific form or grade of the substance complies with the requirements of the monograph. Certain functionality-related tests may be described to control properties that may influence the suitability of the substance and subsequently the properties of dosage forms prepared from it.

Powdered substances may be processed to obtain a certain degree of fineness (2.9.12).

Compacted substances are processed to increase the particle size or to obtain particles of a specific form and/or to obtain a substance with a higher bulk density.

Coated active substances consist of particles of the active substance coated with one or more suitable excipients.

Granulated active substances are particles of a specified size and/or form produced from the active substance by granulation directly or with one or more suitable excipients.

If substances are processed with excipients, these excipients comply with the requirements of the relevant monograph or, where no such monograph exists, the approved specification.

CHARACTERS

The statements under the heading Characters (e.g. statements about the solubility or a decomposition point) are not to be interpreted in a strict sense and are not requirements. They are given for information.

Where a substance may show polymorphism, this may be stated under Characters in order to draw this to the attention of the user who may have to take this characteristic into consideration during formulation of a preparation.

01/2005:2034

SUBSTANCES FOR PHARMACEUTICAL USE

Corpora ad usum pharmaceuticum

The statements in this monograph are intended to be read in conjunction with individual monographs on substances in the Pharmacopoeia. Application of the monograph to other substances may be decided by the competent authority.

DEFINITION

Substances for pharmaceutical use are any organic or inorganic substances that are used as active substances or excipients for the production of medicinal products for human or veterinary use. They may be obtained from natural sources or produced by extraction from raw materials, fermentation or synthesis.

Substances for pharmaceutical use may be used as such or as starting materials for subsequent formulation to prepare medicinal products. Depending on the formulation, certain substances may be used either as active substances or excipients. Solid substances may be compacted, coated, granulated, powdered to a certain fineness or processed in other ways. Processing with addition of excipients is permitted only where this is specifically stated in the Definition of the individual monograph.

Substance for pharmaceutical use of special grade.

Unless otherwise indicated or restricted in the individual monographs, a substance for pharmaceutical use is intended for human and veterinary use, and is of appropriate quality for manufacture of all dosage forms in which it can be used.

IDENTIFICATION

Where under Identification an individual monograph contains subdivisions entitled *First identification* and *Second identification*, the test or tests that constitute the *First identification* may be used in all circumstances. The test or tests that constitute the *Second identification* may be used for identification, provided it can be demonstrated that the substance is fully traceable to a batch certified to comply with all the other requirements of the monograph.

TESTS

Polymorphism (5.9). If the nature of a crystalline or amorphous form imposes restrictions on its use in preparations, the nature of the specific crystalline or amorphous form is identified, its morphology is adequately controlled and its identity is stated on the label.

Related substances. Organic impurities in active substances are to be reported, identified wherever possible, and qualified as indicated in Table 2034.-1.

Specific thresholds may be applied for impurities known to be unusually potent or to produce toxic or unexpected pharmacological effects.

If the individual monograph does not provide suitable control for a new impurity, a suitable test for control must be developed and included in the specification for the substance.

The requirements above do not apply to biological and biotechnological products, peptides, oligonucleotides, radiopharmaceuticals, products of fermentation and semi-synthetic products derived therefrom, to crude products of animal or plant origin or herbal products.

Residual solvents are limited according to the principles defined in the chapter (5.4), using the general method (2.4.24) or other suitable methods. Where a quantitative determination of a residual solvent is carried out and a test for loss on drying is not carried out, the content of residual solvent is taken into account for calculation of the assay content of the substance.

Sterility (2.6.1). If intended for use in the manufacture of sterile dosage forms without a further appropriate sterilisation procedure, or if offered as sterile grade, the substance for pharmaceutical use complies with the test for sterility.

Bacterial endotoxins (2.6.14). If offered as bacterial endotoxin-free grade, the substance for pharmaceutical use complies with the test for bacterial endotoxins. The limit and test method (if not gelation method A) are stated in the individual monograph. The limit is calculated in accordance with *Test for bacterial endotoxins: guidelines* (2.6.14), unless a lower limit is justified from results from production batches or is required by the competent authority. Where a test for bacterial endotoxins is prescribed, a test for pyrogens is not required.

Pyrogens (2.6.8). If the test for pyrogens is justified rather than the test for bacterial endotoxins and if a pyrogen-free grade is offered, the substance for pharmaceutical use complies with the test for pyrogens. The limit and test method are stated in the individual monograph or approved by the competent authority. Based on appropriate test validation for bacterial endotoxins and pyrogens, the test for bacterial endotoxins may replace the test for pyrogens.

Additional properties. Control of additional properties (e.g. physical characteristics, functionality-related characteristics) may be necessary for individual manufacturing processes or formulations. Grades (such as sterile, endotoxin-free, pyrogen-free) may be produced with a view to manufacture of preparations for parenteral administration or other dosage forms and appropriate requirements may be specified in an individual monograph.

ASSAY

Unless justified and authorised, contents of substances for pharmaceutical use are determined. Suitable methods are used.

LABELLING

In general, labelling is subject to supranational and national regulation and to international agreements. The statements under the heading Labelling therefore are not comprehensive and, moreover, for the purposes of the Pharmacopoeia only those statements that are necessary to demonstrate compliance or non-compliance with the monograph are mandatory. Any other labelling statements are included as recommendations. When the term "label" is used in the Pharmacopoeia, the labelling statements may appear on the container, the package, a leaflet accompanying the package or a certificate of analysis accompanying the article, as decided by the competent authority.

Where appropriate, the label includes statements that the substance is:

- intended for a specific use,
- of a distinct crystalline form,
- of a specific degree of fineness,
- compacted,
- coated,
- granulated,
- sterile,
- free from bacterial endotoxins,
- free from pyrogens,
- containing gliding agents.

Where appropriate, the label indicates the degree of hydration, the nature of any added antimicrobial preservative, antioxidant or other excipient. When active substances are processed with addition of excipients, the label indicates the excipients used and the content of active substance and excipients.

Table 2034.-1. – Reporting, identification and qualification of organic impurities in active substances

Use	Maximum daily dose	Reporting threshold	Identification threshold	Qualification threshold
Human use or human and veterinary use	≤ 2 g/day	> 0.05 per cent	> 0.10 per cent or a daily intake of > 1.0 mg (whichever is the lower)	> 0.15 per cent or a daily intake of > 1.0 mg (whichever is the lower)
Human use or human and veterinary use	> 2 g/day	> 0.03 per cent	> 0.05 per cent	> 0.05 per cent
Veterinary use only	Not applicable	> 0.1 per cent	> 0.2 per cent	> 0.5 per cent

01/2005:0153

VACCINES FOR HUMAN USE

Vaccina ad usum humanum

For a combined vaccine, where there is no monograph to cover a particular combination, the vaccine complies with the monograph for each individual component, with any necessary modifications approved by the competent authority.

DEFINITION

Vaccines for human use are preparations containing antigenic substances capable of inducing a specific and active immunity in man against an infecting agent or the toxin or the antigen elaborated by it. They shall have been shown to have acceptable immunogenic activity in man with the intended vaccination schedule.

Vaccines for human use may contain: organisms inactivated by chemical or physical means that maintain adequate immunogenic properties; living organisms that are naturally avirulent or that have been treated to attenuate their virulence whilst retaining adequate immunogenic properties; antigens extracted from the organisms or secreted by them or produced by genetic engineering; the antigens may be used in their native state or may be detoxified by chemical or physical means and may be aggregated, polymerised or conjugated to a carrier to increase their immunogenicity.

Terminology used in monographs on vaccines for human use is defined in chapter 5.2.1.

Bacterial vaccines are suspensions of various degrees of opacity in colourless or almost colourless liquids, or may be freeze-dried. The concentration of living or inactivated bacteria is expressed in terms of International Units of opacity or, where appropriate, is determined by direct cell count or, for living bacteria, by viable count.

Bacterial toxoids are prepared from toxins by diminishing their toxicity to a non-detectable level or by completely eliminating it by physical or chemical procedures whilst retaining adequate immunogenic properties. The toxins are obtained from selected strains of micro-organisms. The method of production is such that the toxoid does not revert to toxin. Toxoids may be liquid or freeze-dried. They may be purified and adsorbed. Adsorbed toxoids are suspensions of white or grey particles dispersed in colourless or pale yellow liquids and may form a sediment at the bottom of the container.

Viral vaccines are prepared from viruses grown in animals, in fertilised eggs, in suitable cell cultures or in suitable tissues or by culture of genetically engineered cells. They are liquids that vary in opacity according to the type of preparation or may be freeze-dried. Liquid preparations and freeze-dried preparations after reconstitution may be coloured if a pH indicator such as phenol red has been used in the culture medium.

PRODUCTION

General provisions. Requirements for production including in-process testing are included in individual monographs. Where justified and authorised, certain tests may be omitted where it can be demonstrated, for example by validation studies, that the production process consistently ensures compliance with the test.

Unless otherwise justified and authorised, vaccines are produced using a seed-lot system. The methods of

preparation are designed to maintain adequate immunogenic properties, to render the preparation harmless and to prevent contamination with extraneous agents.

Unless otherwise justified and authorised, in the production of a final lot of vaccine, the number of passages of a virus, or the number of subcultures of a bacterium, from the master seed lot shall not exceed that used for production of the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy.

Vaccines are as far as possible free from ingredients known to cause toxic, allergic or other undesirable reactions in man. Suitable additives, including stabilisers and adjuvants may be incorporated. Penicillin and streptomycin are not used at any stage of production nor added to the final product; however, master seed lots prepared with media containing penicillin or streptomycin may, where justified and authorised, be used for production.

Substrates for propagation. Substrates for propagation comply with the relevant requirements of the Pharmacopoeia (5.2.2, 5.2.3) or in the absence of such requirements with those of the competent authority. Processing of cell banks and subsequent cell cultures is done under aseptic conditions in an area where no other cells are being handled. Serum and trypsin used in the preparation of cell suspensions shall be shown to be free from extraneous agents.

Seed lots. The strain of bacterium or virus used in a master seed lot is identified by historical records that include information on the origin of the strain and its subsequent manipulation. Suitable measures are taken to ensure that no micro-organism other than the seed strain is present in a seed lot.

Culture media. Culture media are as far as possible free from ingredients known to cause toxic, allergic or other undesirable reactions in man; if inclusion of such ingredients is necessary, it shall be demonstrated that the amount present in the final lot is reduced to such a level as to render the product safe. Approved animal (but not human) serum may be used in the growth medium for cell cultures but the medium used for maintaining cell growth during virus multiplication shall not contain serum, unless otherwise stated. Cell culture media may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration although it is preferable to have a medium free from antibiotics during production.

Propagation and harvest. The seed cultures are propagated and harvested under defined conditions. The purity of the harvest is verified by suitable tests as defined in the monograph.

Control cells. For vaccines produced in cell cultures, control cells are maintained and tested as prescribed. In order to provide a valid control, these cells must be maintained in conditions that are rigorously identical with those used for the production cell cultures, including use of the same batches of media and media changes.

Control eggs. For live vaccines produced in eggs, control eggs are incubated and tested as prescribed in the monograph.

Purification. Where applicable, validated purification procedures may be applied.

Inactivation. Inactivated vaccines are produced using a validated inactivation process whose effectiveness and consistency have been demonstrated. Where there are recognised potential contaminants of a harvest, for example in vaccines produced in eggs from healthy, non-SPF flocks, the inactivation process is also validated with respect to the

potential contaminants. A test for inactivation is carried out as soon as possible after the inactivation process, unless otherwise justified and authorised.

Stability of intermediates. During production of vaccines, intermediates are obtained at various stages and are stored, sometimes for long periods. Such intermediates include:

- seed lots,
- live or inactivated harvests from bacterial or viral cultures,
- purified harvests that may consist of toxins or toxoids, polysaccharides, bacterial or viral suspensions,
- purified antigens,
- adsorbed antigens,
- conjugated polysaccharides,
- final bulk vaccine,
- vaccine in the final closed container stored at a temperature lower than that used for stability studies and intended for release without re-assay.

Except where they are used within a short period of time, stability studies are carried out on the intermediates in the intended storage conditions to establish the expected extent of degradation. For final bulk vaccine, stability studies may be carried out on representative samples in conditions equivalent to those intended to be used for storage. For each intermediate (except for seed lots), a period of validity applicable for the intended storage conditions is established, where appropriate in the light of stability studies.

Final bulk. The final bulk is prepared by aseptically blending the ingredients of the vaccine.

Adsorbents. Vaccines may be adsorbed on aluminium hydroxide, aluminium phosphate, calcium phosphate or other suitable adsorbent; the adsorbents are prepared in special conditions which confer the appropriate physical form and adsorptive properties.

Antimicrobial preservatives. Antimicrobial preservatives are used to prevent spoilage or adverse effects caused by microbial contamination occurring during the use of a vaccine. Antimicrobial preservatives are not included in freeze-dried products. For single-dose liquid preparations, inclusion of antimicrobial preservatives is not normally acceptable. For multidose liquid preparations, the need for effective antimicrobial preservation is evaluated taking into account likely contamination during use and the maximum recommended period of use after breaching of the container. If an antimicrobial preservative is used, it shall be shown that it does not impair the safety or efficacy of the vaccine. Addition of antibiotics as antimicrobial preservatives is not normally acceptable.

During development studies, the effectiveness of the antimicrobial preservative throughout the period of validity shall be demonstrated to the satisfaction of the competent authority.

The efficacy of the antimicrobial preservative is evaluated as described in chapter 5.1.3. If neither the A criteria nor the B criteria can be met, then in justified cases the following criteria are applied to vaccines for human use: bacteria, no increase at 24 h and 7 days, 3 log reduction at 14 days, no increase at 28 days; fungi, no increase at 14 days and 28 days.

Final lot. For vaccines for parenteral administration, the final lot is prepared by aseptically distributing the final bulk into sterile tamper-proof containers which, after freeze-drying where applicable, are closed so as to exclude contamination.

For vaccines for administration by a non-parenteral route, the final lot is prepared by distributing the final bulk under suitable conditions into sterile, tamper-proof containers.

Degree of adsorption. During development of an adsorbed vaccine, the degree of adsorption is evaluated as part of the consistency testing. A release specification for the degree of adsorption is established in the light of results found for batches used in clinical testing. From the stability data generated for the vaccine it must be shown that at the end of the period of validity the degree of adsorption will not be less than for batches used in clinical testing.

Stability. During development studies, maintenance of potency of the final lot throughout the period of validity shall be demonstrated; the loss of potency in the recommended storage conditions is assessed and excessive loss even within the limits of acceptable potency may indicate that the vaccine is unacceptable.

Expiry date. Unless otherwise stated, the expiry date is calculated from the beginning of the assay or from the beginning of the first assay for a combined vaccine. For vaccines stored at a temperature lower than that used for stability studies and intended for release without re-assay, the expiry date is calculated from the date of removal from cold storage. If, for a given vaccine, an assay is not carried out, the expiry date is calculated from the date of an approved stability-indicating test or failing this from the date of freeze-drying or the date of filling into the final containers. For a combined vaccine where components are presented in separate containers, the expiry date is that of the component which expires first.

The expiry date applies to vaccines stored in the prescribed conditions.

Animal tests. In accordance with the provisions of the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes, tests must be carried out in such a way as to use the minimum number of animals and to cause the least pain, suffering, distress or lasting harm. The criteria for judging tests in monographs must be applied in the light of this. For example, if it is indicated that an animal is considered to show positive, infected etc. when typical clinical signs or death occur then as soon as sufficient indication of a positive result is obtained the animal in question shall be either humanely destroyed or given suitable treatment to prevent unnecessary suffering. In accordance with the General Notices, alternative test methods may be used to demonstrate compliance with the monograph and the use of such tests is particularly encouraged when this leads to replacement or reduction of animal use or reduction of suffering.

TESTS

Vaccines comply with the tests prescribed in individual monographs including, where applicable, the following:

Aluminium (2.5.13): maximum 1.25 mg of aluminium (Al) per single human dose where an aluminium adsorbent has been used in the vaccine, unless otherwise stated,

Calcium (2.5.14): maximum 1.3 mg of calcium (Ca) per single human dose where a calcium adsorbent has been used in the vaccine, unless otherwise stated,

Formaldehyde (2.4.18): maximum 0.2 g/l of free formaldehyde is present in the final product where formaldehyde has been used in the preparation of the vaccine, unless otherwise stated.

Phenol (2.5.15): maximum 2.5 g/l is present in the final product where phenol has been used in the preparation of the vaccine, unless otherwise stated.

Water (2.5.12): maximum 3.0 per cent *m/m* for freeze-dried vaccines, unless otherwise stated.

STORAGE

Store protected from light. Unless otherwise stated, the storage temperature is 5 ± 3 °C; liquid adsorbed vaccines must not be allowed to freeze.

LABELLING

The label states:

- the name of the preparation,
- a reference identifying the final lot,
- the recommended human dose and route of administration,
- the storage conditions,
- the expiry date,
- the name and amount of any antimicrobial preservative,
- the name of any antibiotic, adjuvant, flavour or stabiliser present in the vaccine,
- the name of any constituent that may cause adverse reactions and any contra-indications to the use of the vaccine,
- for freeze-dried vaccines:
 - the name or composition and the volume of the reconstituting liquid to be added,
 - the time within which the vaccine is to be used after reconstitution.

VACCINES FOR VETERINARY USE

Vaccina ad usum veterinarium

In the case of combined vaccines, for each component that is the subject of a monograph in the Pharmacopoeia, the provisions of that monograph apply to that component, modified where necessary as indicated (see Tests (Safety) below, Evaluation of safety of veterinary vaccines (5.2.6) and Evaluation of efficacy of veterinary vaccines (5.2.7)).

DEFINITION

Vaccines for veterinary use are preparations containing antigenic substances and are administered for the purpose of inducing a specific and active immunity against disease provoked by bacteria, toxins, viruses, fungi or parasites. The vaccines, live or inactivated, confer active immunity that may be transferred passively via maternal antibodies against the immunogens they contain and sometimes also against antigenically related organisms. Vaccines may contain bacteria, toxins, viruses or fungi, living or inactivated, parasites, or antigenic fractions or substances produced by these organisms and rendered harmless whilst retaining all or part of their antigenic properties; vaccines may also contain combinations of these constituents. The antigens may be produced by recombinant DNA technology. Suitable adjuvants may be included to enhance the immunising properties of the vaccines.

Terminology used in monographs on vaccines for veterinary use is defined in chapter 5.2.1.

BACTERIAL VACCINES AND BACTERIAL TOXOIDS

Bacterial vaccines and bacterial toxoids are prepared from cultures grown on suitable solid or liquid media, or by other suitable means; the requirements of this section do not apply to bacterial vaccines prepared in cell cultures or in

live animals. The strain of bacterium used may have been modified by genetic engineering. The identity, antigenic potency and purity of each bacterial culture used is carefully controlled.

Bacterial vaccines contain inactivated or live bacteria or their antigenic components; they are liquid preparations of various degrees of opacity or they may be freeze-dried.

Bacterial toxoids are prepared from toxins by diminishing their toxicity to a very low level or by completely eliminating it by physical or chemical means whilst retaining adequate immunising potency. The toxins are obtained from selected strains of specified micro-organisms grown in suitable media or are obtained by other suitable means, for example, chemical synthesis.

The toxoids may be:

- liquid,
- precipitated with alum or other suitable agent,
- purified and/or adsorbed on aluminium phosphate, aluminium hydroxide, calcium phosphate or other adsorbent prescribed in the monograph.

Bacterial toxoids are clear or slightly opalescent liquids. Adsorbed toxoids are suspensions or emulsions. Certain toxoids may be freeze-dried.

Unless otherwise indicated, statements and requirements given below for bacterial vaccines apply equally to bacterial vaccines, bacterial toxoids and products containing a combination of bacterial cells and toxoid.

VIRAL VACCINES

Viral vaccines are prepared by growth in suitable cell cultures (5.2.4), in tissues, in micro-organisms, in fertilised eggs or, where no other possibility is available, in live animals, or by other suitable means. The strain of virus used may have been modified by genetic engineering. They are liquid or freeze-dried preparations of one or more viruses or viral subunits or peptides.

Live viral vaccines are prepared from viruses of attenuated virulence or of natural low virulence for the target species.

Inactivated viral vaccines are treated by a validated procedure for inactivation of the virus and may be purified and concentrated.

VECTOR VACCINES

Vector vaccines are liquid or freeze-dried preparations of one or more types of live micro-organisms (bacteria or viruses) that are non-pathogenic or have low pathogenicity for the target species and in which have been inserted one or more genes encoding antigens that stimulate an immune response protective against other microorganisms.

PRODUCTION

The methods of preparation, which vary according to the type of vaccine, are such as to maintain the identity and immunogenicity of the antigen and to ensure freedom from contamination with extraneous agents.

Substances of animal origin used in the production of vaccines for veterinary use comply with the requirements of chapter 5.2.5. Other substances used in the preparation of vaccines for veterinary use comply with requirements of the Pharmacopoeia (where a relevant monograph exists) and are prepared in a manner that avoids contamination of the vaccine.

SUBSTRATES FOR PRODUCTION

Cell cultures used in the production of vaccines for veterinary use comply with the requirements of chapter 5.2.4.

Where a monograph refers to chicken flocks free from specified pathogens (SPF), these flocks comply with the requirements prescribed in chapter 5.2.2.

For production of inactivated vaccines, where vaccine organisms are grown in poultry embryos, such embryos are derived either from SPF flocks (5.2.2) or from healthy non-SPF flocks free from the presence of certain agents and their antibodies, as specified in the monograph. It may be necessary to demonstrate that the inactivation process is effective against specified potential contaminants. For the production of a master seed lot and for all passages of a micro-organism up to and including the working seed lot, eggs from SPF flocks (5.2.2) are used.

Where it is unavoidable to use animals or animal tissues in the production of veterinary vaccines, such animals shall be free from specified pathogens, as appropriate to the source species and the target animal for the vaccine.

MEDIA

At least the qualitative composition must be recorded of media used for seed culture preparation and for production. The grade of each named ingredient is specified. Where media or ingredients are claimed as proprietary, this is indicated and an appropriate description recorded. Ingredients that are derived from animals are specified as to the source species and country of origin, and must comply with the criteria described in chapter 5.2.5. Preparation processes for media used, including sterilisation procedures, are documented.

The addition of antibiotics during the manufacturing process is normally restricted to cell culture fluids and other media, egg inocula and material harvested from skin or other tissues.

BACTERIAL SEED LOTS

General requirements. The genus and species (and varieties where appropriate) of the bacteria used in the vaccine are stated. Bacteria used in manufacture are handled in a seed-lot system wherever possible. Each master seed lot is tested as described below. A record of the origin, date of isolation, passage history (including purification and characterisation procedures) and storage conditions is maintained for each master seed lot. Each master seed lot is assigned a specific code for identification purposes.

Propagation. The minimum and maximum number of subcultures of each master seed lot prior to the production stage are specified. The methods used for the preparation of seed cultures, preparation of suspensions for seeding, techniques for inoculation of seeds, titre and concentration of inocula and the media used, are documented. It shall be demonstrated that the characteristics of the seed material (for example, dissociation or antigenicity) are not changed by these subcultures. The conditions under which each seed lot is stored are documented.

Identity and purity. Each master seed lot is shown to contain only the species and strain of bacterium stated. A brief description of the method of identifying each strain by biochemical, serological and morphological characteristics and distinguishing it as far as possible from related strains is recorded, as is also the method of determining the purity of the strain. If the master seed lot is shown to contain living organisms of any kind other than the species and strain stated, then it is unsuitable for vaccine production.

VIRUS SEED LOTS

General requirements. Viruses used in manufacture are handled in a seed-lot system. Each master seed lot is tested as described below. A record of the origin, date of isolation, passage history (including purification and characterisation procedures) and storage conditions is maintained for each

seed lot. Each master seed lot is assigned a specific code for identification purposes. Production of vaccine is not normally undertaken using virus more than 5 passages from the master seed lot. In the tests on the master seed lot described below, the organisms used are not normally more than 5 passages from the master seed lot at the start of the tests, unless otherwise indicated.

Where the master seed lot is contained within a permanently infected master cell seed, the following tests are carried out on an appropriate volume of virus from disrupted master cell seed. Where relevant tests have been carried out on disrupted cells to validate the suitability of the master cell seed, these tests need not be repeated.

Propagation. The master seed lot and all subsequent passages are propagated on cells, on embryonated eggs or in animals that have been shown to be suitable for vaccine production (see above), and, where applicable, using substances of animal origin that meet the requirements prescribed in chapter 5.2.5.

Identification. A suitable method to identify the vaccine strain and to distinguish it as far as possible from related strains must be used.

Bacterial and fungal contamination. The master seed lot complies with the test for sterility (2.6.1).

Mycoplasmas (2.6.7). The master seed lot complies with the test for mycoplasmas (culture method and indicator cell culture method).

Absence of extraneous viruses. Monographs may contain requirements for freedom from extraneous agents, otherwise the requirements stated below apply.

Preparations of monoclonal or polyclonal antibodies containing high levels of neutralising antibody to the virus of the seed lot are made on a batch basis, using antigen that is not derived from any passage level of the virus isolate giving rise to the master seed virus. Each batch of serum is maintained at 56 °C for 30 min to inactivate complement. Each batch is shown to be free of antibodies to potential contaminants of the seed virus and is shown to be free of any non-specific inhibiting effects on the ability of viruses to infect and propagate within cells (or eggs, where applicable). If such a serum cannot be obtained, other methods are used to remove or neutralise the seed virus specifically.

If the seed lot virus would interfere with the conduct and sensitivity of a test for extraneous viruses, a sample of the master seed lot is treated with a minimum amount of the monoclonal or polyclonal antibody so that the vaccine virus is neutralised as far as possible or removed. The final virus-serum mixture shall, if possible, contain at least the virus content of 10 doses of vaccine per 0.1 ml for avian vaccines and per millilitre for other vaccines. For avian vaccines, the testing to be carried out on seed lots is given in chapters 2.6.3, 2.6.4, 2.6.5 and 2.6.6. For mammalian vaccines, the seed lot or the mixture of seed lot and antiserum is tested for freedom from extraneous agents as follows.

The mixture is inoculated onto cultures of at least 70 cm² of the required cell types. The cultures may be inoculated at any suitable stage of growth up to 70 per cent confluency. At least 1 monolayer of each type must be retained as a control. The cultures must be monitored daily for a week. At the end of this period the cultures are freeze thawed 3 times, centrifuged to remove cell debris and re-inoculated onto the same cell type as above. This is repeated twice. The final passage must produce sufficient cells in appropriate vessels to carry out the tests below.

Cytopathic and haemadsorbing agents are tested for using the methods described in the relevant sections on testing cell cultures (5.2.4) and techniques such as immuno-fluorescence are used for detection of specific contaminants for the tests in cell cultures. The master seed lot is inoculated onto:

- primary cells of the species of origin of the virus,
- cells sensitive to viruses pathogenic for the species for which the vaccine is intended,
- cells sensitive to pestiviruses.

If the master seed lot is shown to contain living organisms of any kind, other than the virus of the species and strain stated, or foreign viral antigens, then it is unsuitable for vaccine production.

INACTIVATION

Inactivated vaccines are subjected to a validated inactivation procedure. The testing of the inactivation kinetics described below is carried out once for a given production process. The rest of this section applies to each production run. When conducting tests for inactivation, it is essential to take account of the possibility that under the conditions of manufacture, organisms may be physically protected from inactivant.

Inactivation kinetics. The inactivating agent and the inactivation procedure shall be shown, under conditions of manufacture, to inactivate the vaccine micro-organism. Adequate data on inactivation kinetics shall be obtained. Normally, the time required for inactivation shall be not more than 67 per cent of the duration of the inactivation process.

Aziridine. If an aziridine compound is used as the inactivating agent then it shall be shown that no inactivating agent remains at the end of the inactivation procedure. This may be accomplished by neutralising the inactivating agent with thiosulphate and demonstrating residual thiosulphate in the inactivated harvest at the completion of the inactivation procedure.

Formaldehyde. If formaldehyde is used as the inactivating agent, then a test for free formaldehyde is carried out as prescribed under Tests.

Other inactivating agents. When other inactivation methods are used, appropriate tests are carried out to demonstrate that the inactivating agent has been removed or reduced to an acceptable residual level.

Inactivation and/or detoxification testing. A test for complete inactivation and/or detoxification is performed immediately after the inactivation and/or detoxification procedure and, if applicable, the neutralisation or removal of the inactivating or detoxifying agent.

Bacterial vaccines. The test selected shall be appropriate to the vaccine bacteria being used and shall consist of at least 2 passages in production medium or, if solid medium has been used for production, in a suitable liquid medium or in the medium prescribed in the monograph. The product complies with the test if no evidence of any live micro-organism is observed.

Bacterial toxoids. The test selected shall be appropriate to the toxin or toxins present and shall be the most sensitive available.

Viral vaccines. The test selected shall be appropriate to the vaccine virus being used and must consist of at least 2 passages in cells, embryonated eggs or, where no other suitably sensitive method is available, in animals. The quantity of cell samples, eggs or animals shall be sufficient to ensure appropriate sensitivity of the test. For tests in cell cultures, not less than 150 cm² of cell culture monolayer is

inoculated with 1.0 ml of inactivated harvest. The product complies with the test if no evidence of the presence of any live virus or other micro-organism is observed.

CHOICE OF VACCINE COMPOSITION AND CHOICE OF VACCINE STRAIN

For the choice of vaccine composition and choice of vaccine strain, important aspects to be evaluated include safety, efficacy and stability. General requirements for evaluation of safety and efficacy are given in chapter 5.2.6 and chapter 5.2.7. These requirements may be made more explicit or supplemented by the requirements of specific monographs.

For live vaccines, a maximum virus titre or bacterial count acceptable from the point of view of safety is established during development studies. This is then used as the maximum acceptable titre for each batch of vaccine at release.

Potency and immunogenicity. The tests given under the headings Potency and Immunogenicity in monographs serve 2 purposes:

- the Potency section establishes by a well-controlled test in experimental conditions, the minimum acceptable vaccinating capacity for all vaccines within the scope of the definition, which must be guaranteed throughout the period of validity;
- well-controlled experimental studies are normally a part of the overall demonstration of efficacy of a vaccine (see chapter 5.2.7); the test referred to in the section 'Immunogenicity' (which is usually a cross-reference to the Potency section) is suitable as a part of this testing.

For most vaccines, the tests cited under Potency or Immunogenicity are not suitable for the routine testing of batches.

For live vaccines, the minimum acceptable virus titre or bacterial count that gives satisfactory results in the Potency test and other efficacy studies is established during development. For routine testing it must be demonstrated for each batch that the titre or count at release is such that at the end of the period of validity, in the light of stability studies, the vaccine, stored in the recommended conditions, will contain not less than the minimum acceptable virus titre or bacterial count determined during development studies. For inactivated vaccines, if the test described under Potency is not used for routine testing, a batch potency test is established during development. The aim of the batch potency test is to ensure that each batch of vaccine would, if tested, comply with the test described under Potency or Immunogenicity. The acceptance criteria for the batch potency test are therefore established by correlation with the test described under Potency. Where a batch potency test is described in a monograph, this is given as an example of a test that is considered suitable, after establishment of correlation with the potency test; other test models can also be used.

Route of administration. During development of a vaccine, safety and immunogenicity are demonstrated for each route of administration to be recommended. The following is a non-exhaustive list of such routes of administration:

- intramuscular,
- subcutaneous,
- intravenous,
- ocular,
- oral,
- nasal,
- foot-stab,
- wing web,

- intradermal,
- intraperitoneal,
- *in ovo*.

Methods of administration. During development of a vaccine, safety and immunogenicity are demonstrated for each method of administration to be recommended. The following is a non-exhaustive list of such methods of administration:

- injection,
- drinking water,
- spray,
- eye-drop,
- scarification,
- implantation,
- immersion.

Categories of animal. Monographs may indicate that a given test is to be carried out for each category of animal of the target species for which the product is recommended or is to be recommended. The following is a non-exhaustive list of categories that are to be taken into account.

- **Mammals:**
 - pregnant animals/non-pregnant animals,
 - animals raised primarily for breeding/animals raised primarily for food production,
 - animals of the minimum age or size recommended for vaccination.
- **Avian species:**
 - birds raised primarily for egg production/birds raised primarily for production of meat,
 - birds before point of lay/birds after onset of lay.
- **Fish:**
 - broodstock fish/fish raised primarily for food production.

Stability. Evidence of stability is obtained to justify the proposed period of validity. This evidence takes the form of the results of virus titrations, bacterial counts or potency tests carried out at regular intervals until 3 months beyond the end of the shelf life on not fewer than 3 representative consecutive batches of vaccine kept under recommended storage conditions together with results from studies of moisture content (for freeze-dried products), physical tests on the adjuvant, chemical tests on substances such as the adjuvant constituents and preservatives and pH, as appropriate.

Where applicable, studies on the stability of the reconstituted vaccine are carried out, using the product reconstituted in accordance with the proposed recommendations.

FINAL BULK VACCINE

The final bulk vaccine is prepared by combining one or more batches of antigen that comply with all the relevant requirements with any auxiliary substances, such as adjuvants, stabilisers, antimicrobial preservatives and diluents.

Antimicrobial preservatives. Antimicrobial preservatives are used to prevent spoilage or adverse effects caused by microbial contamination occurring during use of a vaccine which is expected to be no longer than 10 h after first broaching. Antimicrobial preservatives are not included in freeze-dried products but, if justified, taking into account the maximum recommended period of use after reconstitution, they may be included in the diluent for multi-dose freeze-dried products. For single-dose liquid preparations, inclusion of antimicrobial preservatives is not acceptable unless justified and authorised, but may be acceptable, for

example where the same vaccine is filled in single-dose and multidose containers and is used in non-food-producing species. For multidose liquid preparations, the need for effective antimicrobial preservation is evaluated taking into account likely contamination during use and the maximum recommended period of use after broaching of the container.

During development studies the effectiveness of the antimicrobial preservative throughout the period of validity shall be demonstrated to the satisfaction of the competent authority.

The efficacy of the antimicrobial preservative is evaluated as described in chapter 5.1.3 and in addition samples are tested at suitable intervals over the proposed in use shelf-life. If neither the A criteria nor the B criteria can be met, then in justified cases the following criteria are applied to vaccines for veterinary use: bacteria, no increase from 24 h to 7 days, 3 log reduction at 14 days, no increase at 28 days; fungi, no increase at 14 days and 28 days.

Addition of antibiotics as antimicrobial preservative is generally not acceptable.

Test for inactivation and/or detoxification. For inactivated vaccines, where the auxiliary substances would interfere with a test for inactivation and/or detoxification, a test for inactivation or detoxification is carried out during preparation of the final bulk, after the different batches of antigen have been combined but before addition of auxiliary substances; the test for inactivation or detoxification may then be omitted on the final bulk and the batch.

Where there is a risk of reversion to toxicity, the test for detoxification performed at the latest stage of the production process at which the sensitivity of the test is not compromised (e.g. after the different batches of antigen have been combined but before the addition of auxiliary substances) is important to demonstrate a lack of reversion to toxicity.

In-process tests. Certain tests may be carried out on the final bulk vaccine rather than on the batch or batches prepared from it; such tests include those for antimicrobial preservatives, free formaldehyde and the potency determination for inactivated vaccines.

BATCH

Unless otherwise prescribed in the monograph, the final bulk vaccine is distributed aseptically into sterile, tamper-proof containers which are then closed so as to exclude contamination.

Only a batch that complies with each of the requirements given below under Identification, Tests and Potency or in the relevant individual monograph may be released for use. With the agreement of the competent authority, certain of the batch tests may be omitted where in-process tests give an equal or better guarantee that the batch would comply or where alternative tests validated with respect to the Pharmacopoeia method have been carried out.

The identification test can often be conveniently combined with the batch potency test to avoid unnecessary use of animals. For a given vaccine, a validated *in vitro* test can be used to avoid the unnecessary use of animals.

It is recognised that, in accordance with General Notices (1.1. General statements), for an established vaccine the routine application of the safety test will be waived by the competent authority in the interests of animal welfare when a sufficient number of consecutive production batches have been produced and found to comply with the test, thus demonstrating consistency of the manufacturing process. Significant changes to the manufacturing process may require resumption of routine testing to re-establish consistency. The number of consecutive batches to be tested

depends on a number of factors such as the type of vaccine, the frequency of production of batches and experience with the vaccine during development safety testing and during application of the batch safety test. Without prejudice to the decision of the competent authority in the light of information available for a given vaccine, testing of 10 consecutive batches is likely to be sufficient for most products. For products with an inherent safety risk, it may be necessary to continue to conduct the safety test on each batch.

Animal tests. In accordance with the provisions of the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes, tests must be carried out in such a way as to use the minimum number of animals and to cause the least pain, suffering, distress or lasting harm. The criteria for judging tests in monographs must be applied in the light of this. For example, if it is indicated that an animal is considered to be positive, infected etc. when typical clinical signs occur then as soon as it is clear that the result will not be affected the animal in question shall be either humanely killed or given suitable treatment to prevent unnecessary suffering. In accordance with the General Notices, alternative test methods may be used to demonstrate compliance with the monograph and the use of such tests is particularly encouraged when this leads to replacement or reduction of animal use or reduction of suffering.

Physical tests. A vaccine with an oily adjuvant is tested for viscosity by a suitable method and shown to be within the limits set for the product. The stability of the emulsion shall be demonstrated.

Chemical tests. Tests for the concentrations of appropriate substances such as aluminium and preservatives are carried out to show that these are within the limits set for the product.

pH. The pH of liquid products and diluents is measured and shown to be within the limits set for the product.

Water. Where applicable, the freeze-drying process is checked by a determination of water and shown to be within the limits set for the product.

IDENTIFICATION

For inactivated vaccines, the identification prescribed in monographs is usually an antibody induction test since this is applicable to all vaccines.

TESTS

The monographs also indicate tests to be carried out on each particular vaccine.

All hen eggs, chickens and chicken cell cultures for use in quality control tests shall be derived from an SPF flock (5.2.2).

Formaldehyde (2.4.18; use Method B if sodium metabisulphite has been used to neutralise excess formaldehyde). Where formaldehyde has been used in the preparation, the concentration of free formaldehyde is not greater than 0.5 g/l, unless a higher amount has been shown to be safe.

Phenol (2.5.15). When the vaccine contains phenol, the concentration is not greater than 5 g/l.

Sterility (2.6.1). Where prescribed in the monograph, vaccines comply with the test for sterility. Where the volume of liquid in a container is greater than 100 ml, the method of membrane filtration is used wherever possible. Where the method of membrane filtration cannot be used, the method

of direct inoculation may be used. Where the volume of liquid in each container is at least 20 ml, the minimum volume to be used for each culture medium is 10 per cent of the contents or 5 ml, whichever is less. The appropriate number of items to be tested (2.6.1) is 1 per cent of the batch with a minimum of 4 and a maximum of 10.

For avian live viral vaccines, for non-parenteral use only, the requirement for sterility is usually replaced by requirements for absence of pathogenic micro-organisms and for a maximum of 1 non-pathogenic micro-organism per dose.

Extraneous agents. Monographs prescribe a set of measures that taken together give an acceptable degree of assurance that the final product does not contain infectious extraneous agents. These measures include:

- 1) Production within a seed-lot system and a cell-seed system, wherever possible;
- 2) Extensive testing of seed lots and cell seed for extraneous agents;
- 3) Requirements for SPF flocks used for providing substrates for vaccine production;
- 4) Testing of substances of animal origin, which must, wherever possible, undergo an inactivation procedure;
- 5) For live vaccines, testing of the final product for infectious extraneous agents; such tests are less extensive than those carried out at earlier stages because of the guarantees given by in-process testing.

In cases of doubt, the tests intended for the seed lot of a live vaccine may also be applied to the final product. If an extraneous agent is found in such a test, the vaccine does not comply the monograph.

Avian live viral vaccines comply with the tests for extraneous agents in batches of finished products (2.6.4).

Mycoplasmas (2.6.7). Where prescribed in a monograph, the vaccine complies with the test for mycoplasmas (culture method).

Safety. In general, 2 doses of an inactivated vaccine and/or 10 doses of a live vaccine are injected by a recommended route. It may be necessary to reduce the prescribed number of doses under certain circumstances or amend the method of re-constitution and injection, for example for a combined vaccine, where it is difficult to reconstitute 10 doses of the live component in 2 doses of the inactivated component. The animals are observed for the longest period stated in the monographs. No abnormal local or systemic reaction occurs. Where several batches are prepared from the same final bulk, the safety test is carried out on the first batch and then omitted for further batches prepared from the same final bulk.

During development studies, the type and degree of reactions expected with the vaccine are defined in the light of safety testing. This definition is then used as part of the operating procedure for the batch safety test to evaluate acceptable and unacceptable reactions.

The immune status of animals to be used for the safety test is specified in the individual monograph. For most monographs, one of the 3 following categories is specified:

- 1) the animals must be free from antibodies against the virus/bacterium/toxin etc. contained in the vaccine,
- 2) the animals are preferably free from antibodies but animals with a low level of antibody may be used as long as the animals have not been vaccinated and the administration of the vaccine does not cause an anamnestic response,
- 3) the animals must not have been vaccinated against the disease the vaccine is intended to prevent.

As a general rule, category 1 is specified for live vaccines. For other vaccines, category 2 is usually specified but where most animals available for use in tests would comply with category 1, this may be specified for inactivated vaccines also. Category 3 is specified for some inactivated vaccines where determination of antibodies prior to testing is unnecessary or impractical. For poultry vaccines, as a general rule the use of SPF birds is specified.

For avian vaccines, the safety test is generally carried out using 10 SPF chickens (5.2.2), except that for vaccines not recommended for use in chickens it is carried out using 10 birds of one of the species for which the vaccine is recommended, the birds being free from antibodies against the disease agent for which the vaccine is intended to provide protection.

POTENCY

See Choice of vaccine composition and choice of vaccine strain under Production.

STORAGE

Store protected from light at a temperature of 5 ± 3 °C, unless otherwise indicated. Liquid preparations are not to be allowed to freeze, unless otherwise indicated.

LABELLING

The label states:

- that the preparation is for veterinary use,
- the volume of the preparation and the number of doses in the container,
- the route of administration,
- the type or types of bacteria or viruses used and for live vaccines the minimum and the maximum number of live bacteria or the minimum and the maximum virus titre,
- where applicable, for inactivated vaccines, the minimum potency in International Units,
- where applicable, the name and amount of antimicrobial preservative or other substance added to the vaccine,
- the name of any substance that may cause an adverse reaction,
- for freeze-dried vaccines:
 - the name or composition and the volume of the reconstituting liquid to be added,
 - the period within which the vaccine is to be used after reconstitution,
- for vaccines with an oily adjuvant, that if the vaccine is accidentally injected into man, urgent medical attention is necessary,
- the animal species for which the vaccine is intended,
- the indications for the vaccine,
- the instructions for use,
- any contra-indications to the use of the product including any required warning on the dangers of administration of an overdose,
- the doses recommended for different species.

01/2005:1579

VEGETABLE FATTY OILS

Olea herbaria

DEFINITION

Vegetable fatty oils are mainly solid or liquid triglycerides of fatty acids. They may contain small amounts of other lipids such as waxes, free fatty acids, partial glycerides or

unsaponifiable matters. Vegetable fatty oils are obtained from the seeds, the fruit or the pit/stone/kernel of various plants by expression and/or solvent extraction, then possibly refined and hydrogenated. A suitable antioxidant may be added if necessary.

Virgin oil: an oil obtained from raw materials of special quality by mechanical procedures (e.g. by cold expression or centrifugation).

Refined oil: an oil obtained by expression and/or solvent extraction, and subsequently, either alkali refining (followed by bleaching and deodorisation) or physical refining.

Hydrogenated oil: an oil obtained by expression and/or solvent extraction, and subsequently, either alkali refining or physical refining, then possible bleaching, followed by drying, hydrogenation and subsequent bleaching and deodorisation.

Only phosphoric acid and alkali refined oils are used in the preparation of parenteral dosage forms.

PRODUCTION

OBTAINING OF A CRUDE OIL

When the plant has a high oil content, the oil is generally obtained by expression under heating followed by an extraction; when the plant has a low oil content, the oil is generally obtained by direct extraction.

Mechanical procedures

A. Expression

High-pressure screw-pressing. It consists of some or all of the following steps: cleaning, drying, dehulling or decorticating, grinding, cooking and flaking.

During *cleaning* the foreign matter is eliminated. *Drying* may be necessary if the seed moisture content is higher than desirable for downstream processing. *Decorticating* is useful to obtain a high-protein meal by reduction of fibre and to reduce impurities in the oil. *Cooking* serves various purposes: completion of the breakdown of oil cells, lowering of the viscosity of the oil, coagulation of the protein in the meal, adjustment of the moisture level, sterilisation of the seed, detoxifying undesirable seed constituents (gossypol for cottonseed) and fixing certain phosphatides in the cake thus lowering subsequent refining losses. The efficacy of the expression process is such that only 3 per cent to 6 per cent of the oil is left in the cake.

Wet screw-pressing. The bunches are loaded into cages (for palm fruit) and moved into a horizontal steriliser with application of live steam and heating. The purposes of this steriliser are inactivation of enzymes, loosening of the fruit on the bunch, coagulation of proteins, etc. After heating in a digester, the pulp is fed to a screw-press. The oil is centrifugally clarified and vacuum-dried.

Pre-pressing followed by solvent extraction. The same sequence of steps is performed as above. The main function of pre-pressing is to obtain a cake of excellent permeability for the following solvent extraction stage. The extraction is performed either in a percolation type or in an immersion type apparatus. The efficacy of the solvent extraction process is such that residual oil levels in meal are generally below 1 per cent.

B. Centrifugation

Centrifugation separates the oily phase from the aqueous phase which contains water, water-soluble components and residual solid particles. This operation can be carried out using:

- self-cleaning bowl or disc centrifuges,

- super-decanter, which are horizontal turbines equipped with a cylindrical bowl that tapers slightly at one end and which contains a continuously turning screw that scrapes the sides of the bowl. The screw and the bowl rotate at different speeds. The solid particles are discarded from the tapered end of the bowl and the oil flows out from the other end.

Solvent extraction. Prior to extraction, the following steps are carried out: the seeds are tempered for about a week at a temperature below 24 °C in order to loosen the hull from the seed and allow the seed moisture to attain equilibrium. Then the seeds are cleaned, ground, dehulled and flaked. The most widely used solvent is a mixture of mainly *n*-hexane and methylpentanes (bp: 65-70 °C) commonly referred to as “hexane”. Due to the major fire and explosive risks of this mixture, liquified gases and supercritical gases may also be used.

REFINING

The objective of refining is to remove impurities and contaminants of the oil with the least possible damage to the triglycerides and with minimal loss of oil. The contents of the following substances are reduced:

- free fatty acids which may cause deterioration of the oil by oxidation, smoked taste when heated and sharp flavour (by alkali refining),
- water which favours the enzymatic hydrolysis reactions (by alkali refining, drying),
- partial glycerides which may cause foaming and bitter taste (by neutralisation, washing),
- phosphatides and phosphorous compounds which have emulsifying properties, may cause deposits, a darkening of the oil when heated, a cloudy appearance and bad organoleptic stability (by alkali refining),
- colouring matters such as chlorophyll (by alkali refining), carotenoids (by bleaching),
- glycolipids which may form colloidal solutions with water,
- free hydrocarbons, paraffin, waxes and resinous materials,
- metals (Fe, Cu, Pb, Sn, Pt, Pd, etc.) which are strong oxidation catalysts,
- pigments such as gossypol (in cottonseed oil) or mycotoxins such as aflatoxin (mainly in arachis oil),
- pesticides,
- oxidation products (aldehydes, peroxides),
- proteins having possible allergic reactions,
- unsaponifiable matters (e.g. lignins, sterols, tocopherols and other vitamins),
- polycyclic aromatic hydrocarbons.

Alkali refining. It involves the following steps: degumming, neutralisation using alkali, washing and drying.

Degumming. During this step of the refining, i.e. treatment with water and/or phosphoric acid, and/or sodium chloride, the phosphatides, phosphorous compounds and metals are eliminated. The use of this step depends on the nature of the oil.

Neutralisation with alkali. This step reduces the free fatty acid content below 0.1 per cent; the fatty acids are converted into oil-insoluble soaps, also called “soapstocks”. Other substances may be removed by adsorption on these soaps: mucilaginous substances, phosphatides, oxidation products, colouring matters, etc. All substances that become insoluble in the oil on hydration are removed. Neutralisation with alkali has the disadvantage of saponifying a portion of neutral oil if the neutralisation is not well conducted.

Washing. This operation consists in removing the excess of soaps and alkali as well as the remaining traces of metals, phosphatides and other impurities, using hot water.

Drying. The remaining water is eliminated under vacuum before any further steps, such as bleaching.

Physical refining. It involves a steam treatment of the oil under high vacuum at a temperature greater than 235 °C. This technique must be applied to oils naturally low in phosphatides and metals (palm, coconut, olive) or from which phosphatides and metals have been removed by an acid treatment using concentrated phosphoric acid followed by an adsorptive treatment with activated bleaching earth (for sunflower, rapeseed, soya-bean). Moreover it cannot be used for heat sensitive oils (cottonseed oil) which darken.

Bleaching. The common method of bleaching is by adsorption treatment of the oil, which is generally heated at 90 °C for 30 min under vacuum, with bleaching earth (natural or activated) or carbon (activated or not); synthetic silica adsorbents may also be added. Substances which have not been totally removed during refining are eliminated, for example carotenoids and chlorophyll.

Deodorisation. Deodorisation eliminates odours, volatile substances and residual extraction solvents; it involves injecting dry vapour into the oil which is kept under vacuum at a high temperature. Different temperatures are used according to the oil: 200 °C to 235 °C for 1 h 30 min to 3 h or greater than 240 °C for 30 min.

One of the main side reactions is thermic decolourisation due to the destruction of carotenoids when the temperature is greater than 150 °C. This technique provokes a loss of substances which may be distilled (free fatty acids, sterols, tocopherols, part of the refined oil) and may cause *cis-trans* isomerisation of the unsaturated fatty-acid double bonds.

WINTERISATION

Elimination of solids and waxes by filtration at low temperature (also called dewaxing). These solids and waxes could affect the appearance of the oil and cause deposits.

HYDROGENATION

The hydrogenation of the dried and/or bleached oil is performed using a catalyst (e.g. Ni, Pt, Pd), at a temperature of about 100 °C to 200 °C under hydrogen pressure. The catalyst is then removed by filtration at 90 °C. The hydrogen must be pure: free of poisons for the catalyst, water-free, low in carbon dioxide, methane and nitrogen contents. Small amounts of *trans*-fatty acids or polymers may be obtained.

CHROMATOGRAPHIC PURIFICATION

In high purity applications, mainly for parenteral uses, the oil may be further purified by passing the oil through a column containing an activated earth. A solvent may sometimes be used to improve the efficiency. High polarity molecules such as oxidised materials, acids, alcohols, partial glycerides and free sterols are preferentially removed.

When the oil is used in the preparation of parenteral dosage forms, the limits set in the monograph for the acid value, the peroxide value and the water content may be different.

LABELLING

The label states:

- where applicable, that the oil was obtained by expression or extraction,
- where applicable, that the oil is suitable for use in the manufacture of parenteral dosage forms,
- the name and concentration of any added antioxidant.

01/2005:1502 **Large-volume parenterals**

Infusions and injections supplied in containers with a nominal content of more than 100 ml.

Small-volume parenterals

Infusions and injections supplied in containers with a nominal content of 100 ml or less.

01/2005:0016

GLOSSARY

The following introductory text provides definitions and/or explanations of terms that may be found in, or used in association with, the general monographs on dosage forms, but that are not defined within them. Where relevant, reference is made to other equivalent terms that may be found in other publications or contexts.

This glossary is published for information.

Standard Term

Standard Terms for describing the pharmaceutical form of a medicinal product, the routes of administration and the containers used have been established by the European Pharmacopoeia Commission and are provided in a separate publication on Standard Terms.

Active substance

Equivalent terms: active ingredient, drug substance, medicinal substance, active pharmaceutical ingredient.

Vehicle

A vehicle is the carrier, composed of one or more excipients, for the active substance(s) in a liquid preparation.

Basis

A basis is the carrier, composed of one or more excipients, for the active substance(s) in semi-solid and solid preparations.

Conventional-release dosage forms

Conventional-release dosage forms are preparations showing a release of the active substance(s) which is not deliberately modified by a special formulation design and/or manufacturing method. In the case of a solid dosage form, the dissolution profile of the active substance depends essentially on its intrinsic properties. Equivalent term: immediate-release dosage form.

Modified-release dosage forms

Modified-release dosage forms are preparations where the rate and/or place of release of the active substance(s) is different from that of a conventional-release dosage form administered by the same route. This deliberate modification is achieved by a special formulation design and/or manufacturing method. Modified-release dosage forms include prolonged-release, delayed-release and pulsatile-release dosage forms.

Prolonged-release dosage forms

Prolonged-release dosage forms are modified-release dosage forms showing a slower release of the active substance(s) than that of a conventional-release dosage form administered by the same route. Prolonged-release is achieved by a special formulation design and/or manufacturing method. Equivalent term: extended-release dosage form.

Delayed-release dosage forms

Delayed-release dosage forms are modified-release dosage forms showing a release of the active substance(s) which is delayed. Delayed release is achieved by a special formulation design and/or manufacturing method. Delayed-release dosage forms include gastro-resistant preparations as defined in the general monographs on solid oral dosage forms.

Pulsatile-release dosage forms

Pulsatile-release dosage forms are modified-release dosage forms showing a sequential release of the active substance(s). Sequential release is achieved by a special formulation design and/or manufacturing method.

CAPSULES

Capsulae

The requirements of this monograph do not necessarily apply to preparations that are presented as capsules intended for use other than by oral administration. Requirements for such preparations may be found, where appropriate, in other general monographs, for example Rectal preparations (1145) and Vaginal preparations (1164).

DEFINITION

Capsules are solid preparations with hard or soft shells of various shapes and capacities, usually containing a single dose of active substance. They are intended for oral administration.

The capsule shells are made of gelatin or other substances, the consistency of which may be adjusted by the addition of substances such as glycerol or sorbitol. Excipients such as surface-active agents, opaque fillers, antimicrobial preservatives, sweeteners, colouring matter authorised by the competent authority and flavouring substances may be added. The capsules may bear surface markings.

The contents of capsules may be solid, liquid or of a paste-like consistency. They consist of one or more active substances with or without excipients such as solvents, diluents, lubricants and disintegrating agents. The contents do not cause deterioration of the shell. The shell, however, is attacked by the digestive fluids and the contents are released.

Where applicable, containers for capsules comply with the requirements of *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

Several categories of capsules may be distinguished:

- hard capsules,
- soft capsules,
- gastro-resistant capsules,
- modified-release capsules,
- cachets.

PRODUCTION

In the manufacture, packaging, storage and distribution of capsules, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, capsules with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test B for uniformity of content of single-dose preparations. If the preparation has more than one active substance, the requirement applies only to those ingredients which correspond to the above conditions.

Uniformity of mass (2.9.5). Capsules comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

Dissolution. A suitable test may be carried out to demonstrate the appropriate release of the active substance(s), for example one of the tests described in *Dissolution test for solid dosage forms (2.9.3)*.

Where a dissolution test is prescribed, a disintegration test may not be required.

STORAGE

Store at a temperature not exceeding 30 °C.

LABELLING

The label states the name of any added antimicrobial preservative.

Hard capsules

DEFINITION

Hard capsules have shells consisting of two prefabricated cylindrical sections one end of which is rounded and closed, the other being open.

PRODUCTION

The active substance(s) usually in solid form (powder or granules) are filled into one of the sections which is then closed by slipping the other section over it. The security of the closure may be strengthened by suitable means.

TESTS

Disintegration. Hard capsules comply with the test for disintegration of tablets and capsules (2.9.1). Use *water R* as the liquid medium. When justified and authorised, *0.1 M hydrochloric acid* or *artificial gastric juice R* may be used as the liquid medium. If the capsules float on the surface of the water, a disc may be added. Operate the apparatus for 30 min, unless otherwise justified and authorised and examine the state of the capsules. The capsules comply with the test if all 6 have disintegrated.

Soft capsules

DEFINITION

Soft capsules have thicker shells than those of hard capsules. The shells consist of one part and are of various shapes.

PRODUCTION

Soft capsules are usually formed, filled and sealed in one operation but for extemporaneous use, the shell may be prefabricated. The shell material may contain an active substance.

Liquids may be enclosed directly; solids are usually dissolved or dispersed in a suitable vehicle to give a solution or dispersion of a paste-like consistency.

There may be partial migration of the constituents from the capsule contents into the shell and vice versa because of the nature of the materials and the surfaces in contact.

TESTS

Disintegration. Soft capsules comply with the test for disintegration of tablets and capsules (2.9.1). Use *water R* as the liquid medium. When justified and authorised, *0.1 M hydrochloric acid* or *artificial gastric juice R* may be used as the liquid medium. Add a disc to each tube. Liquid active

substances dispensed in soft capsules may attack the disc; in such circumstances and where authorised, the disc may be omitted. Operate the apparatus for 30 min, unless otherwise justified and authorised and examine the state of the capsules. If the capsules fail to comply because of adherence to the discs, repeat the test on a further 6 capsules omitting the discs. The capsules comply with the test if all 6 have disintegrated.

Modified-release capsules

DEFINITION

Modified-release capsules are hard or soft capsules in which the contents or the shell or both contain special excipients or are prepared by a special process designed to modify the rate, the place or the time at which the active substance(s) are released.

Modified release capsules include prolonged-release capsules and delayed-release capsules.

PRODUCTION

A suitable test is carried out to demonstrate the appropriate release of the active substance(s).

Gastro-resistant capsules

DEFINITION

Gastro-resistant capsules are delayed-release capsules that are intended to resist the gastric fluid and to release their active substance or substances in the intestinal fluid. Usually they are prepared by filling capsules with granules or with particles covered with a gastro-resistant coating or in certain cases, by providing hard or soft capsules with a gastro-resistant shell (enteric capsules).

PRODUCTION

For capsules filled with granules or filled with particles covered with a gastro-resistant coating, a suitable test is carried out to demonstrate the appropriate release of the active substance(s).

TESTS

Disintegration. For capsules with a gastro-resistant shell carry out the test for disintegration (2.9.1) with the following modifications. Use *0.1 M hydrochloric acid* as the liquid medium and operate the apparatus for 2 h, or other such time as may be authorised, without the discs. Examine the state of the capsules. The time of resistance to the acid medium varies according to the formulation of the capsules to be examined. It is typically 2 h to 3 h but even with authorised deviations it must not be less than 1 h. No capsule shows signs of disintegration or rupture permitting the escape of the contents. Replace the acid by *phosphate buffer solution pH 6.8 R*. When justified and authorised, a buffer solution of pH 6.8 with added pancreas powder (for example, 0.35 g of *pancreas powder R* per 100 ml of buffer solution) may be used. Add a disc to each tube. Operate the apparatus for 60 min and examine the state of the capsules. If the capsules fail to comply because of adherence to the discs, repeat the test on a further 6 capsules omitting the discs. The capsules comply with the test if all 6 have disintegrated.

Dissolution. For capsules prepared from granules or particles already covered with a gastro-resistant coating, a suitable test is carried out to demonstrate the appropriate release of the active substance(s), for example the test described in *Dissolution test for solid dosage forms (2.9.3)*.

Cachets

DEFINITION

Cachets are solid preparations consisting of a hard shell containing a single dose of one or more active substances. The cachet shell is made of unleavened bread usually from rice flour and consists of 2 prefabricated flat cylindrical sections. Before administration, the cachets are immersed in water for a few seconds, placed on the tongue and swallowed with a draught of water.

LABELLING

The label states the method of administration of the cachets.

01/2005:1239

CHEWING GUMS, MEDICATED

Masticabilia gummis medicata

DEFINITION

Medicated chewing gums are solid, single-dose preparations with a base consisting mainly of gum that are intended to be chewed but not swallowed.

They contain one or more active substances which are released by chewing. After dissolution or dispersion of the active substances in saliva, chewing gums are intended to be used for:

- local treatment of mouth diseases,
- systemic delivery after absorption through the buccal mucosa or from the gastrointestinal tract.

PRODUCTION

Medicated chewing gums are made with a tasteless masticatory gum base that consists of natural or synthetic elastomers. They may contain other excipients such as fillers, softeners, sweetening agents, flavouring substances, stabilisers and plasticisers and authorised colouring matter.

Medicated chewing gums are manufactured by compression or by softening or melting the gum bases and adding successively the other substances. In the latter case, chewing gums are then further processed to obtain the desired gum presentation. The medicated chewing gums may be coated, for example, if necessary to protect from humidity and light.

Unless otherwise justified and authorised, a suitable test is carried out to demonstrate the appropriate release of the active ingredient(s).

In the manufacture, packaging, storage and distribution of medicated chewing gums, suitable means must be taken to ensure their microbial quality; recommendations related to this aspect are provided in the general chapter on *Microbiological quality of pharmaceutical preparations* (5.1.4).

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, medicated chewing gums with a content of active ingredient less than 2 mg or less than 2 per cent of the total mass comply with test A for uniformity of content of single-dose preparations. If the preparation contains more than one active substance, the requirement applies only to those active substances which correspond to the above conditions.

Uniformity of mass (2.9.5). Uncoated medicated chewing gums and, unless otherwise justified and authorised, coated medicated chewing gums comply with the test for uniformity

of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

STORAGE

Store uncoated medicated chewing gums protected from humidity and light.

01/2005:0652

EAR PREPARATIONS

Auricularia

DEFINITION

Ear preparations are liquid, semi-solid or solid preparations intended for instillation, for spraying, for insufflation, for application to the auditory meatus or as an ear wash.

Ear preparations usually contain one or more active substances in a suitable vehicle. They may contain excipients, for example, to adjust tonicity or viscosity, to adjust or stabilise the pH, to increase the solubility of the active substances, to stabilise the preparation or to provide adequate antimicrobial properties. The excipients do not adversely affect the intended medicinal action of the preparation or, at the concentrations used, cause toxicity or undue local irritation.

Preparations for application to the injured ear, particularly where the ear-drum is perforated, or prior to surgery are sterile, free from antimicrobial preservatives and supplied in single-dose containers.

Ear preparations are supplied in multi-dose or single-dose containers, provided, if necessary, with a suitable administration device which may be designed to avoid the introduction of contaminants.

Unless otherwise justified and authorised, aqueous ear preparations supplied in multidose containers contain a suitable antimicrobial preservative at a suitable concentration, except where the preparation itself has adequate antimicrobial properties.

Where applicable, containers for ear preparations comply with the requirements of *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

Several categories of ear preparations may be distinguished:

- ear-drops and sprays,
- semi-solid ear preparations,
- ear powders,
- ear washes,
- ear tampons.

PRODUCTION

During the development of an ear preparation, the formulation for which contains an antimicrobial preservative, the effectiveness of the chosen preservative shall be demonstrated to the satisfaction of the competent authority. A suitable test method together with criteria for judging the preservative properties of the formulation are provided in the text on *Efficacy of antimicrobial preservation* (5.1.3).

In the manufacture, packaging, storage and distribution of ear preparations, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

Sterile ear preparations are prepared using materials and methods designed to ensure sterility and to avoid the introduction of contaminants and the growth of

micro-organisms; recommendations on this aspect are provided in the text on *Methods of preparation of sterile products* (5.1.1).

In the manufacture of ear preparations containing dispersed particles, measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, single-dose ear preparations with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test B for uniformity of content of single-dose preparations. If the preparation has more than one active substance, the requirement applies only to those ingredients that correspond to the above conditions.

Uniformity of mass (2.9.5). Single-dose ear preparations comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

Sterility (2.6.1). Where the label indicates that the ear preparation is sterile, it complies with the test for sterility.

STORAGE

If the preparation is sterile, store in a sterile, airtight, tamper-proof container.

LABELLING

The label states:

- the name of any added antimicrobial preservative,
- where applicable, that the preparation is sterile,
- for multidose containers, the period after opening the container after which the contents must not be used. This period does not exceed 4 weeks, unless otherwise justified and authorised.

Ear-drops and sprays

DEFINITION

Ear-drops and sprays are solutions, emulsions or suspensions of one or more active substances in liquids suitable for application to the auditory meatus without exerting harmful pressure on the ear-drum (for example, water, glycols or fatty oils). They may also be placed in the auditory meatus by means of a tampon impregnated with the liquid.

Emulsions may show evidence of phase separation but are readily redispersed on shaking. Suspensions may show a sediment which is readily dispersed on shaking to give a suspension which remains sufficiently stable to enable the correct dose to be delivered.

Ear drops are usually supplied in multidose containers of glass or suitable plastic material that are fitted with an integral dropper or with a screw cap of suitable materials incorporating a dropper and rubber or plastic teat. Alternatively, such a cap assembly is supplied separately. Sprays are usually supplied in multi-dose containers fitted with an appropriate applicator. When sprays are supplied in pressurised containers, these comply with the requirements of the monograph on *Pressurised pharmaceutical preparations* (0523).

Semi-solid ear preparations

DEFINITION

Semi-solid ear preparations are intended for application to the external auditory meatus, if necessary by means of a tampon impregnated with the preparation.

Semi-solid ear preparations comply with the requirements of the monograph on *Semi-solid preparations for cutaneous application* (0132).

They are supplied in containers fitted with a suitable applicator.

Ear powders

DEFINITION

Ear powders comply with the requirements of the monograph on *Powders for cutaneous application* (1166).

They are supplied in containers fitted with a suitable device for application or insufflation.

Ear washes

DEFINITION

Ear washes are preparations intended to cleanse the external auditory meatus. They are usually aqueous solutions with apH within physiological limits.

Ear washes intended for application to injured parts or prior to a surgical operation are sterile.

TESTS

Deliverable mass or volume (2.9.28). Ear washes supplied in single-dose containers comply with the test.

Ear tampons

DEFINITION

Ear tampons are intended to be inserted into the external auditory meatus. They comply with the requirements of the monograph on *Medicated tampons* (1155).

01/2005:1163

EYE PREPARATIONS

Ophthalmica

DEFINITION

Eye preparations are sterile liquid, semi-solid or solid preparations intended for administration upon the eyeball and/or to the conjunctiva or for insertion in the conjunctival sac.

Where applicable, containers for eye preparations comply with the requirements of *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

Several categories of eye preparations may be distinguished:

- eye drops,
- eye lotions,
- powders for eye drops and eye lotions,
- semi-solid eye preparations,
- ophthalmic inserts.

PRODUCTION

During the development of an eye preparation, the formulation for which contains an antimicrobial preservative, the effectiveness of the chosen preservative shall be demonstrated to the satisfaction of the competent authority. A suitable test method together with criteria for judging the preservative properties of the formulation are provided in the text on *Efficacy of antimicrobial preservation* (5.1.3).

Eye preparations are prepared using materials and methods designed to ensure sterility and to avoid the introduction of contaminants and the growth of micro-organisms; recommendations on this aspect are provided in the text on *Methods of preparation of sterile products* (5.1.1).

In the manufacture of eye preparations containing dispersed particles, measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

TESTS

Sterility (2.6.1). Eye preparations comply with the test for sterility. Applicators supplied separately also comply with the test for sterility. Remove the applicator with aseptic precautions from its package and transfer it to a tube of culture medium so that it is completely immersed. Incubate and interpret the results as described in the test for sterility.

Deliverable mass or volume (2.9.28). Liquid and semi-solid eye preparations supplied in single-dose containers comply with the test.

STORAGE

Unless otherwise prescribed, store in a sterile, airtight, tamper-proof container.

LABELLING

The label states the name of any added antimicrobial preservative.

Eye-drops

DEFINITION

Eye-drops are sterile aqueous or oily solutions or suspensions of one or more active substances intended for instillation into the eye.

Eye-drops may contain excipients, for example, to adjust the tonicity or the viscosity of the preparation, to adjust or stabilise the pH, to increase the solubility of the active substance, or to stabilise the preparation. These substances do not adversely affect the intended medicinal action or, at the concentrations used, cause undue local irritation.

Aqueous preparations supplied in multidose containers contain a suitable antimicrobial preservative in appropriate concentration except when the preparation itself has adequate antimicrobial properties. The antimicrobial preservative chosen must be compatible with the other ingredients of the preparation and must remain effective throughout the period of time during which eye-drops are in use.

If eye-drops are prescribed without antimicrobial preservatives they are supplied wherever possible in single-dose containers. Eye-drops intended for use in surgical procedures do not contain antimicrobial preservatives and are supplied in single-dose containers.

Eye-drops that are solutions, examined under suitable conditions of visibility, are practically clear and practically free from particles.

Eye-drops that are suspensions may show a sediment that is readily redispersed on shaking to give a suspension which remains sufficiently stable to enable the correct dose to be delivered.

Multidose preparations are supplied in containers that allow successive drops of the preparation to be administered. The containers contain at most 10 ml of the preparation, unless otherwise justified and authorised.

TESTS

Particle size. Unless otherwise justified and authorised, eye-drops in the form of a suspension comply with the following test: introduce a suitable quantity of the suspension into a counting cell or with a micropipette onto a slide, as appropriate, and scan under a microscope an area corresponding to 10 µg of the solid phase. For practical reasons, it is recommended that the whole sample is first scanned at low magnification (e.g. × 50) and particles greater than 25 µm are identified. These larger particles can then be measured at a larger magnification (e.g. × 200 to × 500). For each 10 µg of solid active substance, not more than 20 particles have a maximum dimension greater than 25 µm, and not more than 2 of these particles have a maximum dimension greater than 50 µm. None of the particles has a maximum dimension greater than 90 µm.

LABELLING

The label states for multidose containers, the period after opening the container after which the contents must not be used. This period does not exceed 4 weeks, unless otherwise justified and authorised.

Eye lotions

DEFINITION

Eye lotions are sterile aqueous solutions intended for use in washing or bathing the eye or for impregnating eye dressings. Eye lotions may contain excipients, for example to adjust the tonicity or the viscosity of the preparation or to adjust or stabilise the pH. These substances do not adversely affect the intended action or, at the concentrations used, cause undue local irritation.

Eye lotions supplied in multidose containers contain a suitable antimicrobial preservative in appropriate concentration except when the preparation itself has adequate antimicrobial properties. The antimicrobial preservative chosen is compatible with the other ingredients of the preparation and remains effective throughout the period of time during which the eye lotions are in use.

If eye lotions are prescribed without an antimicrobial preservative, they are supplied in single-dose containers. Eye lotions intended for use in surgical procedures or in first-aid treatment do not contain an antimicrobial preservative and are supplied in single-dose containers.

Eye lotions examined under suitable conditions of visibility, are practically clear and practically free from particles.

The containers for multidose preparations do not contain more than 200 ml of eye lotion, unless otherwise justified and authorised.

LABELLING

The label states:

- where applicable, that the contents are to be used on one occasion only,
- for multidose preparations, the period after opening the container after which the contents must not be used. This period does not exceed 4 weeks, unless otherwise justified and authorised.

Powders for eye-drops and powders for eye lotions

DEFINITION

Powders for the preparation of eye-drops and eye lotions are supplied in a dry, sterile form to be dissolved or suspended in an appropriate liquid vehicle at the time of administration.

They may contain excipients to facilitate dissolution or dispersion, to prevent caking, to adjust the tonicity, to adjust or stabilise the pH or to stabilise the preparation.

After dissolution or suspension in the prescribed liquid, they comply with the requirements for eye-drops or eye lotions, as appropriate.

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, single-dose powders for eye-drops and eye lotions with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test B for uniformity of content of single-dose preparations. If the preparation has more than one active substance, the requirement applies only to those substances which correspond to the above condition.

Uniformity of mass (2.9.5). Single-dose powders for eye-drops and eye lotions comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

Semi-solid eye preparations

DEFINITION

Semi-solid eye preparations are sterile ointments, creams or gels intended for application to the conjunctiva. They contain one or more active substances dissolved or dispersed in a suitable basis. They have a homogeneous appearance.

Semi-solid eye preparations comply with the requirements of the monograph on *Semi-solid preparations for cutaneous application (0132)*. The basis is non-irritant to the conjunctiva.

Semi-solid eye preparations are packed in small, sterilised collapsible tubes fitted or provided with a cannula and having a content of not more than 5 g of the preparation. The tubes must be well-closed to prevent microbial contamination. Semi-solid eye preparations may also be packed in suitably designed single-dose containers. The containers, or the nozzles of tubes, are of such a shape as to facilitate administration without contamination. Tubes are tamper-proof.

TESTS

Particle size. Semi-solid eye preparations containing dispersed solid particles comply with the following test: spread gently a quantity of the preparation corresponding to at least 10 µg of solid active substance as a thin layer. Scan under a microscope the whole area of the sample. For practical reasons, it is recommended that the whole sample is first scanned at a small magnification (e.g. $\times 50$) and particles greater than 25 µm are identified. These larger particles can then be measured at a larger magnification (e.g. $\times 200$ to $\times 500$). For each 10 µg of solid active substance, not more than 20 particles have a maximum dimension greater than 25 µm, and not more than 2 of these particles have a maximum dimension greater than 50 µm. None of the particles has a maximum dimension greater than 90 µm.

Ophthalmic inserts

DEFINITION

Ophthalmic inserts are sterile, solid or semi-solid preparations of suitable size and shape, designed to be inserted in the conjunctival sac, to produce an ocular effect. They generally consist of a reservoir of active substance embedded in a matrix or bounded by a rate-controlling

membrane. The active substance, which is more or less soluble in physiological fluids, is released over a determined period of time.

Ophthalmic inserts are individually distributed into sterile containers.

PRODUCTION

In the manufacture of ophthalmic inserts, means must be taken to ensure a suitable dissolution behaviour.

TESTS

Uniformity of content (2.9.6). Ophthalmic inserts comply, where applicable, with test A for uniformity of content.

LABELLING

The label states:

- where applicable, the total quantity of active substance per insert,
- where applicable, the dose released per unit time.

01/2005:1105

FOAMS, MEDICATED

Musci medicati

Additional requirements for medicated foams may be found, where appropriate, in other general monographs, for example on Rectal preparations (1145), Vaginal preparations (1164) and Liquid preparations for cutaneous application (0927).

DEFINITION

Medicated foams are preparations consisting of large volumes of gas dispersed in a liquid generally containing one or more active substances, a surfactant ensuring their formation and various other excipients. Medicated foams are usually intended for application to the skin or mucous membranes.

Medicated foams are usually formed at the time of administration from a liquid preparation in a pressurised container. The container is equipped with a device consisting of a valve and a push button suitable for the delivery of the foam.

Medicated foams intended for use on severely injured skin and on large open wounds are sterile.

Medicated foams supplied in pressurised containers comply with the requirements of the monograph on *Pressurised pharmaceutical preparations (0523)*.

PRODUCTION

Sterile medicated foams are prepared using materials and methods designed to ensure sterility and to avoid the introduction of contaminants and the growth of micro-organisms; recommendations on this aspect are provided in the text on *Methods of preparation of sterile products (5.1.1)*.

TESTS

Relative foam density. Maintain the container at about 25 °C for at least 24 h. Taking care not to warm the container, fit a rigid tube 70 mm to 100 mm long and about 1 mm in internal diameter onto the push button. Shake the container to homogenise the liquid phase of the contents and dispense 5 ml to 10 ml of foam to waste. Tare a flat-bottomed dish with a volume of about 60 ml and about 35 mm high. Place the end of the rigid tube attached to the push button in the corner of the dish, press the push button and fill the dish uniformly, using a circular motion. After the foam has

completely expanded, level off by removing the excess foam with a slide. Weigh. Determine the mass of the same volume of *water R* by filling the same dish with *water R*.

The relative foam density is equivalent to the ratio:

$$\frac{m}{e}$$

m = mass of the test sample of foam, in grams,

e = mass of same volume of *water R*, in grams.

Carry out three measurements. None of the individual values deviate by more than 20 per cent from the mean value.

Duration of expansion. The apparatus (Figure 1105-1) consists of a 50 ml burette, 15 mm in internal diameter, with 0.1 ml graduations and fitted with a 4 mm single bore stopcock. The graduation corresponding to 30 ml is at least 210 mm from the axis of the stopcock. The lower part of the burette is connected by means of a plastic tube not longer than 50 mm and 4 mm in internal diameter to the foam-generating container equipped with a push button fitted to this connection. Maintain the container at about 25 °C for at least 24 h. Shake the container, taking care not to warm it, to homogenise the liquid phase of the contents and dispense 5 ml to 10 ml of the foam to waste. Connect the push button to the outlet of the burette. Press the button and introduce about 30 ml of foam in a single delivery. Close the stopcock and at the same time start the chronometer and read the volume of foam in the burette. Every 10 s read the growing volume until the maximum volume is reached.

Carry out three measurements. None of the times needed to obtain the maximum volume is more than 5 min.

Figure 1105-1. – Apparatus for the determination of the duration of expansion

Sterility (2.6.1). When the label indicates that the preparation is sterile, it complies with the test for sterility.

LABELLING

The label states, where applicable, that the preparation is sterile.

01/2005:0499

GRANULES

Granulata

Requirements for granules to be used for the preparation of oral solutions or suspensions are given in the monograph on Liquid preparations for oral use (0672). Where justified and authorised, the requirements of this monograph do not apply to granules for veterinary use.

DEFINITION

Granules are preparations consisting of solid, dry aggregates of powder particles sufficiently resistant to withstand handling. They are intended for oral administration. Some are swallowed as such, some are chewed and some are dissolved or dispersed in water or another suitable liquid before being administered.

Granules contain one or more active substances with or without excipients and, if necessary, colouring matter authorised by the competent authority and flavouring substances.

Granules are presented as single-dose or multidose preparations. Each dose of a multidose preparation is administered by means of a device suitable for measuring the quantity prescribed. For single-dose granules, each dose is enclosed in an individual container, for example a sachet or a vial.

Where applicable, containers for granules comply with the requirements of *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

Several categories of granules may be distinguished:

- effervescent granules,
- coated granules,
- gastro-resistant granules,
- modified-release granules.

PRODUCTION

In the manufacture, packaging, storage and distribution of granules, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, single-dose granules with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test B for uniformity of content of single-dose preparations. If the preparation has more than one active substance, the requirement applies only to those substances which correspond to the above conditions.

Uniformity of mass (2.9.5). Single-dose granules except for coated granules comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

Uniformity of mass of delivered doses from multidose containers (2.9.27). Granules supplied in multidose containers comply with the test.

STORAGE

If the preparation contains volatile ingredients or the contents have to be protected, store in an airtight container.

Effervescent granules

DEFINITION

Effervescent granules are uncoated granules generally containing acid substances and carbonates or hydrogen carbonates which react rapidly in the presence of water to release carbon dioxide. They are intended to be dissolved or dispersed in water before administration.

TESTS

Disintegration. Place one dose of the effervescent granules in a beaker containing 200 ml of *water R* at 15-25 °C; numerous bubbles of gas are evolved. When the evolution of gas around the individual grains ceases, the granules have disintegrated, being either dissolved or dispersed in the water. Repeat the operation on 5 other doses. The preparation complies with the test if each of the 6 doses used disintegrates within 5 min.

STORAGE

In an airtight container.

Coated granules

DEFINITION

Coated granules are usually multidose preparations and consist of granules coated with one or more layers of mixtures of various excipients.

PRODUCTION

The substances used as coatings are usually applied as a solution or suspension in conditions in which evaporation of the vehicle occurs.

TESTS

Dissolution. A suitable test may be carried out to demonstrate the appropriate release of the active substance(s), for example one of the tests described in *Dissolution test for solid dosage forms (2.9.3)*.

Modified-release granules

DEFINITION

Modified-release granules are coated or uncoated granules which contain special excipients or which are prepared by special procedures, or both, designed to modify the rate, the place or the time at which the active substance or substances are released.

Modified-release granules include prolonged-release granules and delayed-release granules.

PRODUCTION

A suitable test is carried out to demonstrate the appropriate release of the active substance(s).

TESTS

Dissolution. Carry out a suitable test to demonstrate the appropriate release of the active substance(s), for example the test described in *Dissolution test for solid dosage forms (2.9.3)*.

Gastro-resistant granules

DEFINITION

Gastro-resistant granules are delayed-release granules that are intended to resist the gastric fluid and to release the active substance(s) in the intestinal fluid. These properties are achieved by covering the granules with a gastro-resistant material (enteric-coated granules) or by other suitable means.

PRODUCTION

A suitable test is carried out to demonstrate the appropriate release of the active substance(s).

TESTS

Dissolution. Carry out a suitable test to demonstrate the appropriate release of the active substance(s), for example the test described in *Dissolution test for solid dosage forms (2.9.3)*.

01/2005:0945

INTRAMAMMARY PREPARATIONS FOR VETERINARY USE

Praeparationes intramammariae ad usum veterinarium

DEFINITION

Intramammary preparations for veterinary use are sterile preparations intended for introduction into the mammary gland via the teat canal. There are two main categories: those intended for administration to lactating animals, and those intended for administration to animals at the end of lactation or to non-lactating animals for the treatment or prevention of infection.

Intramammary preparations for veterinary use are solutions, emulsions or suspensions or semi-solid preparations containing one or more active substances in a suitable vehicle. They may contain excipients such as stabilising, emulsifying, suspending and thickening agents. Suspensions may show a sediment which is readily dispersed on shaking. Emulsions may show evidence of phase separation but are readily redispersed on shaking.

Unless otherwise justified and authorised, intramammary preparations for veterinary use are supplied in containers for use on one occasion only for introduction in a single teat canal of an animal.

If supplied in multidose containers, aqueous preparations contain a suitable antimicrobial preservative at a suitable concentration, except where the preparation itself has adequate antimicrobial properties. Precautions for administration and for storage between administrations must be taken.

Where applicable, containers for intramammary preparations for veterinary use comply with the requirements of *Materials used for the manufacture of containers (3.1 and subsections)* and *Containers (3.2 and subsections)*.

PRODUCTION

During the development of a intramammary preparation for veterinary use, the formulation for which contains an antimicrobial preservative, the effectiveness of the chosen preservative shall be demonstrated to the satisfaction of the competent authority. A suitable test method together with criteria for judging the preservative properties of the formulation are provided in the text on *Efficacy of antimicrobial preservation (5.1.3)*.

Intramammary preparations for veterinary use are prepared using materials and methods designed to ensure sterility and to avoid the introduction of contaminants and the growth of micro-organisms; recommendations on this aspect are provided in the text on *Methods of preparation of sterile products* (5.1.1).

In the manufacture of intramammary preparations for veterinary use containing dispersed particles, measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

TESTS

Deliverable mass or volume. Squeeze out as much as possible of the contents of ten containers according to the instructions on the label. The mean mass or volume does not differ by more than 10 per cent from the nominal mass or volume.

Sterility (2.6.1). Intramammary preparations for veterinary use comply with the test for sterility; use the technique of membrane filtration or, in justified cases, direct inoculation of the culture media. Squeeze out the contents of ten containers and mix thoroughly. For each medium, use 0.5 g to 1 g (or 0.5 ml to 1 ml as appropriate) taken from the mixed sample.

STORAGE

Store in a sterile, airtight, tamper-proof container.

LABELLING

The label states:

- the name of the active substance(s) and the mass or number of International Units of the active substance(s) that may be delivered from the container using normal technique,
- whether the preparation is intended for use in a lactating animal or a non-lactating animal,
- in the case of multidose containers, the name of any added antimicrobial preservative.

01/2005:1228

INTRARUMINAL DEVICES

Praeparationes intraruminales

The requirements of this monograph do not apply to preparations (sometimes known as boluses), such as large conventional tablets, capsules or moulded dosage forms which give immediate or prolonged release of the active substance(s). Such preparations comply with the relevant parts of the monographs on Capsules (0016) or Tablets (0478).

DEFINITION

Intraruminal devices are solid preparations each containing one or more active substances. They are intended for oral administration to ruminant animals and are designed to be retained in the rumen to deliver the active substance(s) in a continuous or pulsatile manner. The period of release of the active substance(s) may vary from days to weeks according to the nature of the formulation and/or the delivery device.

Intraruminal devices may be administered using a balling gun. Some intraruminal devices are intended to float on the surface of the ruminal fluid while others are intended to remain on the floor of the rumen or reticulum. Each device has a density appropriate for its intended purpose.

PRODUCTION

For continuous release, the intraruminal device is designed to release the active substance(s) at a defined rate over a defined period of time. This may be achieved by erosion, corrosion, diffusion, osmotic pressure or any other suitable chemical, physical or physico-chemical means.

For pulsatile-release, the intraruminal device is designed to release a specific quantity of active substance(s) at one or several defined intermediate times. This may be achieved by corrosion by ruminal fluids of the metallic elements of the intraruminal device which leads to sequential release of the constituent units which are usually in the form of tablets.

In the manufacture of intraruminal devices, means are taken to ensure an appropriate release of the active substance(s).

In the manufacture, packaging, storage and distribution of intraruminal devices, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

TESTS

Uniformity of content (2.9.6). Unless otherwise justified and authorised, constituent tablet units of intraruminal devices in which the active substances are present at levels less than 2 mg or less than 2 per cent of the total mass comply with test A for uniformity of content of single-dose preparations. If the preparation contains more than one active substance, the requirement applies only to those substances which correspond to the above conditions.

Uniformity of mass (2.9.5). Unless otherwise justified and authorised, the constituent tablet units of intraruminal devices comply with the test for uniformity of mass. If the test for uniformity of content is prescribed for all active substances, the test for uniformity of mass is not required.

LABELLING

The label states:

- for continuous-release devices, the dose released per unit time,
- for pulsatile-release devices, the dose released at specified times.

01/2005:0927

LIQUID PREPARATIONS FOR CUTANEOUS APPLICATION

Praeparationes liquidae ad usum dermicum

Where justified and authorised, the requirements of this monograph do not apply to preparations intended for systemic and veterinary use.

DEFINITION

Liquid preparations for cutaneous application are preparations of a variety of viscosities intended for local or transdermal delivery of active ingredients. They are solutions, emulsions or suspensions which may contain one or more active substances in a suitable vehicle. They may contain suitable antimicrobial preservatives, antioxidants and other excipients such as stabilisers, emulsifiers and thickeners.

Emulsions may show evidence of phase separation but are readily redispersed on shaking. Suspensions may show a sediment which is readily dispersed on shaking to give a suspension which is sufficiently stable to enable a homogeneous preparation to be delivered.

Where applicable, containers for liquid preparations for cutaneous application comply with the requirements of *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

When liquid preparations for cutaneous application are dispensed in pressurised containers, the containers comply with the requirements of the monograph on *Pressurised pharmaceutical preparations* (0523).

Preparations specifically intended for use on severely injured skin are sterile.

Several categories of liquid preparations for cutaneous application may be distinguished, for example:

- shampoos,
- cutaneous foams.

PRODUCTION

During the development of a liquid preparation for cutaneous application, the formulation for which contains an antimicrobial preservative, the effectiveness of the chosen preservative shall be demonstrated to the satisfaction of the competent authority. A suitable test method together with criteria for judging the preservative properties of the formulation are provided in the text on *Efficacy of antimicrobial preservation* (5.1.3).

In the manufacture, packaging, storage and distribution of liquid preparations for cutaneous application, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

Sterile liquid preparations for cutaneous application are prepared using materials and methods designed to ensure sterility and to avoid the introduction of contaminants and the growth of micro-organisms; recommendations on this aspect are provided in the text on *Methods of preparation of sterile products* (5.1.1).

In the manufacture of liquid preparations for cutaneous application containing dispersed particles, measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

TESTS

Deliverable mass or volume (2.9.28). Liquid preparations for cutaneous application supplied in single-dose containers comply with the test.

Sterility (2.6.1). Where the label indicates that the preparation is sterile, it complies with the test for sterility.

STORAGE

If the preparation is sterile, store in a sterile, airtight, tamper-proof container.

LABELLING

The label states:

- the name of any added antimicrobial preservative,
- where applicable, that the preparation is sterile.

Shampoos

DEFINITION

Shampoos are liquid or, occasionally semi-solid preparations intended for application to the scalp and subsequent washing away with water. Upon rubbing with water they usually form a foam.

They are emulsions, suspensions or solutions. Shampoos normally contain surface active agents.

Cutaneous foams

DEFINITION

Cutaneous foams comply with the requirements of the monograph on *Medicated foams* (1105).

01/2005:0672

LIQUID PREPARATIONS FOR ORAL USE

Praeparationes liquidae peroraliae

Where justified and authorised, the requirements of this monograph do not apply to liquid preparations for oral use intended for veterinary use.

DEFINITION

Liquid preparations for oral use are usually solutions, emulsions or suspensions containing one or more active substances in a suitable vehicle; they may, however, consist of liquid active substances used as such (oral liquids).

Some preparations for oral use are prepared by dilution of concentrated liquid preparations, or from powders or granules for the preparation of oral solutions or suspensions, for oral drops or for syrups, using a suitable vehicle.

The vehicle for any preparations for oral use is chosen having regard to the nature of the active substance(s) and to provide organoleptic characteristics appropriate to the intended use of the preparation.

Liquid preparations for oral use may contain suitable antimicrobial preservatives, antioxidants and other excipients such as dispersing, suspending, thickening, emulsifying, buffering, wetting, solubilising, stabilising, flavouring and sweetening agents and colouring matter, authorised by the competent authority.

Emulsions may show evidence of phase separation but are readily redispersed on shaking. Suspensions may show a sediment which is readily dispersed on shaking to give a suspension which remains sufficiently stable to enable the correct dose to be delivered.

Where applicable, containers for liquid preparations for oral use comply with the requirements of *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

Several categories of preparations may be distinguished:

- oral solutions, emulsions and suspensions,
- powders and granules for oral solutions and suspensions,
- oral drops,
- powders for oral drops,
- syrups,
- powders and granules for syrups.

PRODUCTION

During the development of a preparation for oral use, the formulation for which contains an antimicrobial preservative, the effectiveness of the chosen preservative shall be demonstrated to the satisfaction of the competent authority. A suitable test method together with criteria for judging the preservative properties of the formulation are provided in the text on *Efficacy of antimicrobial preservation* (5.1.3).

In the manufacturing, packaging, storage and distribution of liquid preparations for oral use, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

In the manufacture of liquid preparations for oral use containing dispersed particles, measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, single-dose preparations that are suspensions comply with the following test. After shaking, empty each container as completely as possible and carry out the test on the individual contents. They comply with test B for uniformity of content of single-dose preparations.

Uniformity of mass. Single-dose preparations that are solutions or emulsions comply with the following test: weigh individually the contents of 20 containers, emptied as completely as possible, and determine the average mass. Not more than 2 of the individual masses deviate by more than 10 per cent from the average mass and none deviates by more than 20 per cent.

Dose and uniformity of dose of oral drops. Into a suitable, graduated cylinder, introduce by means of the dropping device the number of drops usually prescribed for one dose or introduce by means of the measuring device, the usually prescribed quantity. The dropping speed does not exceed 2 drops per second. Weigh the liquid, repeat the addition, weigh again and carry on repeating the addition and weighing until a total of 10 masses are obtained. No single mass deviates by more than 10 per cent from the average mass. The total of 10 masses does not differ by more than 15 per cent from the nominal mass of 10 doses. If necessary, measure the total volume of 10 doses. The volume does not differ by more than 15 per cent from the nominal volume of 10 doses.

Deliverable mass or volume (2.9.28). Liquid preparations for oral use supplied in single-dose containers comply with the test.

Uniformity of mass of delivered doses from multidose containers (2.9.27). Liquid preparations for oral use supplied in multidose containers comply with the test.

LABELLING

The label states the name of any added antimicrobial preservative.

Oral solutions, emulsions and suspensions

DEFINITION

Oral solutions, emulsions and suspensions are supplied in single-dose or multi-dose containers. Each dose from a multi-dose container is administered by means of a device suitable for measuring the prescribed volume. The device is usually a spoon or a cup for volumes of 5 ml or multiples thereof or an oral syringe for other volumes.

Powders and granules for oral solutions and suspensions

DEFINITION

Powders and granules for the preparation of oral solutions or suspensions generally conform to the definitions in the monographs on *Oral powders (1165)* or *Granules (0499)* as appropriate. They may contain excipients in particular to facilitate dispersion or dissolution and to prevent caking.

After dissolution or suspension, they comply with the requirements for oral solutions or oral suspensions, as appropriate.

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, single-dose powders and single-dose granules with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test B for uniformity of content of single-dose preparations. If the preparation has more than one active substance, the requirement applies only to those substances that correspond to the above conditions.

Uniformity of mass (2.9.5). Single-dose powders and single-dose granules comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

LABELLING

The label states:

- the method of preparation of the solution or suspension,
- the conditions and the duration of storage after constitution.

Oral drops

DEFINITION

Oral drops are solutions, emulsions or suspensions which are administered in small volumes such as drops by the means of a suitable device.

LABELLING

The label states the number of drops per millilitre of preparation or per gram of preparation if the dose is measured in drops.

Powders for oral drops

DEFINITION

Powders for the preparation of oral drops generally conform to the definition of *Oral powders (1165)*. They may contain excipients to facilitate dissolution or suspension in the prescribed liquid or to prevent caking.

After dissolution or suspension, they comply with the requirements for oral drops.

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, single-dose powders for oral drops with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test B for uniformity of content of single-dose preparations. If the preparation has more than one active substance, the requirement applies only to those substances that correspond to the above conditions.

Uniformity of mass (2.9.5). Single-dose powders for oral drops comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

Syrups

DEFINITION

Syrups are aqueous preparations characterised by sweet taste and a viscous consistency. They may contain sucrose at a concentration of at least 45 per cent *m/m*. The sweet taste can also be obtained by using other polyols or sweetening agents. Syrups usually contain aromatic or other flavouring agents. Each dose from a multi-dose container is

administered by means of a device suitable for measuring the prescribed volume. The device is usually a spoon or a cup for volumes of 5 ml or multiples thereof.

LABELLING

The label states the name and concentration of the polyol or sweetening agent.

Powders and granules for syrups

DEFINITION

Powders and granules for syrups generally conform to the definitions in the monograph on *Oral powders (1165)* or *Granules (0499)*. They may contain excipients to facilitate dissolution.

After dissolution, they comply with the requirements for syrups.

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, single-dose powders and granules for syrups with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test B for uniformity of content of single-dose preparations. If the preparation has more than one active substance, the requirement applies only to those substances that correspond to the above conditions.

Uniformity of mass (2.9.5). Single-dose powders and granules for syrups comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

- nasal powders,
- semi-solid nasal preparations,
- nasal washes,
- nasal sticks.

PRODUCTION

During the development of a nasal preparation, the formulation for which contains an antimicrobial preservative, the effectiveness of the chosen preservative shall be demonstrated to the satisfaction of the competent authority. A suitable test method together with criteria for judging the preservative properties of the formulation are provided in the text on *Efficacy of antimicrobial preservation (5.1.3)*.

In the manufacture, packaging, storage and distribution of nasal preparations, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations (5.1.4)*.

Sterile nasal preparations are prepared using materials and methods designed to ensure sterility and to avoid the introduction of contaminants and the growth of micro-organisms; recommendations on this aspect are provided in the text on *Methods of preparation of sterile products (5.1.1)*.

In the manufacture of nasal preparations containing dispersed particles, measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

TESTS

Sterility (2.6.1). Where the label states that the preparation is sterile, it complies with the test for sterility.

STORAGE

If the preparation is sterile, store in a sterile, airtight, tamper-proof container.

LABELLING

The label states:

- the name of any added antimicrobial preservative,
- where applicable, that the preparation is sterile.

Nasal drops and liquid nasal sprays

DEFINITION

Nasal drops and liquid nasal sprays are solutions, emulsions or suspensions intended for instillation or spraying into the nasal cavities.

Emulsions may show evidence of phase separation but are easily redispersed on shaking. Suspensions may show a sediment which is readily dispersed on shaking to give a suspension which remains sufficiently stable to enable the correct dose to be delivered.

Nasal drops are usually supplied in multidose containers provided with a suitable applicator.

Liquid nasal sprays are supplied in containers with atomising devices or in pressurised containers fitted with a suitable adapter and with or without a metering dose valve, which comply with the requirements of the monograph on *Pressurised pharmaceutical preparations (0523)*.

The size of droplets of the spray is such as to localise their deposition in the nasal cavity.

TESTS

Unless otherwise prescribed or justified and authorised, nasal drops supplied in single-dose containers and single doses of metered nasal sprays intended for systemic action, comply with the following tests.

01/2005:0676

NASAL PREPARATIONS

Nasalia

DEFINITION

Nasal preparations are liquid, semi-solid or solid preparations intended for administration to the nasal cavities to obtain a systemic or local effect. They contain one or more active substances. Nasal preparations are as far as possible non-irritating and do not adversely affect the functions of the nasal mucosa and its cilia. Aqueous nasal preparations are usually isotonic and may contain excipients, for example, to adjust the viscosity of the preparation, to adjust or stabilise the pH, to increase the solubility of the active substance, or to stabilise the preparation.

Nasal preparations are supplied in multidose or single-dose containers, provided, if necessary, with a suitable administration device which may be designed to avoid the introduction of contaminants.

Unless otherwise justified and authorised, aqueous nasal preparations supplied in multidose containers contain a suitable antimicrobial preservative in appropriate concentration, except where the preparation itself has adequate antimicrobial properties.

Where applicable, the containers comply with the requirements of *Materials used for the manufacture of containers (3.1 and subsections)* and *Containers (3.2 and subsections)*.

Several categories of nasal preparations may be distinguished:

- nasal drops and liquid nasal sprays,

Uniformity of mass. Nasal drops that are solutions comply with the following test: weigh individually the contents of ten containers emptied as completely as possible, and determine the average mass. Not more than two of the individual masses deviate by more than 10 per cent from the average mass and none deviates by more than 20 per cent.

Metered-dose nasal sprays that are solutions comply with the following test: discharge once to waste. Wait for not less than 5 s and discharge again to waste. Repeat this procedure for a further three actuations. Weigh the mass of the container, discharge once to waste and weigh the remaining mass of the container. Calculate the difference between the two masses. Repeat the procedure for a further nine containers. They comply with the test if not more than two of the individual values deviate by more than 25 per cent from the average value and none deviates by more than 35 per cent.

Uniformity of content (2.9.6). Nasal drops that are suspensions or emulsions comply with the following test: empty each container as completely as possible and carry out the test on the individual content. They comply with test B of uniformity of content.

Uniformity of delivered dose. Metered-dose nasal sprays that are suspensions or emulsions comply with the following test. Use an apparatus capable of quantitatively retaining the dose leaving the actuator of the atomising device.

Shake a container for 5 s and discharge once to waste. Wait for not less than 5 s, shake for 5 s and discharge again to waste. Repeat this procedure for a further three actuations. After 2 s, fire one dose of the metered-dose nasal spray into the collecting vessel by actuating the atomising device. Collect the contents of the collecting vessel by successive rinses. Determine the content of active substance in the combined rinses.

Repeat the procedure for a further nine containers.

Unless otherwise justified and authorised, the preparation complies with the test if not more than one of the individual contents is outside the limits of 75 per cent to 125 per cent and none is outside the limits of 65 per cent and 135 per cent of the average content.

If two or three individual contents are outside the limits of 75 per cent to 125 per cent but within the limits of 65 per cent to 135 per cent, repeat the test for twenty more containers. The preparation complies with the test if not more than three individual contents of the thirty individual contents are outside the limits of 75 per cent to 125 per cent and none is outside the limits of 65 per cent to 135 per cent of the average content.

Nasal powders

DEFINITION

Nasal powders are powders intended for insufflation into the nasal cavity by means of a suitable device.

They comply with the requirements of the monograph on *Powders for cutaneous application (1166)*.

The size of the particles is such as to localise their deposition in the nasal cavity and verified by adequate methods of particle-size determination.

Semi-solid nasal preparations

DEFINITION

Semi-solid nasal preparations comply with the requirements of the monograph on *Semi-solid preparations for cutaneous application (0132)*.

The containers are adapted to deliver the product to the site of application.

Nasal washes

DEFINITION

Nasal washes are generally aqueous isotonic solutions intended to cleanse the nasal cavities.

Nasal washes intended for application to injured parts or prior to a surgical operation are sterile.

TESTS

Deliverable mass or volume (2.9.28). Nasal washes supplied in single-dose containers comply with the test.

Nasal sticks

DEFINITION

Nasal sticks comply with the monograph on *Sticks (1154)*.

01/2005:1807

OROMUCOSAL PREPARATIONS

Praeparationes buccales

This monograph does not apply to dental preparations or to preparations such as chewable tablets (0478), medicated chewing gums (1239), oral lyophilisates and other solid or semi-solid preparations that are intended to be chewed or dispersed in the saliva before being swallowed. Where justified and authorised, this monograph does not apply to preparations for veterinary use.

DEFINITION

Oromucosal preparations are solid, semi-solid or liquid preparations, containing one or more active substances intended for administration to the oral cavity and/or the throat to obtain a local or systemic effect. Preparations intended for a local effect may be designed for application to a specific site within the oral cavity such as the gums (gingival preparations) or the throat (oropharyngeal preparations). Preparations intended for a systemic effect are designed to be absorbed primarily at one or more sites on the oral mucosa (e.g. sublingual preparations). Mucoadhesive preparations are intended to be retained in the oral cavity by adhesion to the mucosal epithelium and may modify systemic drug absorption at the site of application. For many oromucosal preparations, it is likely that some proportion of the active substance(s) will be swallowed and may be absorbed via the gastrointestinal tract.

Oromucosal preparations may contain suitable antimicrobial preservatives and other excipients such as dispersing, suspending, thickening, emulsifying, buffering, wetting, solubilising, stabilising, flavouring and sweetening agents. Solid preparations may in addition contain glidants, lubricants and excipients capable of modifying the release of the active substance(s).

Where applicable, containers for oromucosal preparations comply with the requirements for *Materials used for the manufacture of containers (3.1 and subsections)* and *Containers (3.2 and subsections)*.

Several categories of preparations for oromucosal use may be distinguished:

- gargles,
- mouthwashes,
- gingival solutions,
- oromucosal solutions and oromucosal suspensions,

- semi-solid oromucosal preparations (including for example gingival gel, gingival paste, oromucosal gel, oromucosal paste),
- oromucosal drops, oromucosal sprays and sublingual sprays (including oropharyngeal sprays),
- lozenges and pastilles,
- compressed lozenges,
- sublingual tablets and buccal tablets,
- oromucosal capsules,
- mucoadhesive preparations.

PRODUCTION

During the development of an oromucosal preparation containing an antimicrobial preservative, the effectiveness of the chosen preservative shall be demonstrated to the satisfaction of the competent authority. A suitable test method together with the criteria for judging the preservative properties of the formulation are provided in *5.1.3 Efficacy of antimicrobial preservation*.

In the manufacture, packaging, storage and distribution of oromucosal preparations, suitable means are taken to ensure their microbiological quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations (5.1.4)*.

In the manufacture of semi-solid and liquid oromucosal preparations containing dispersed particles, measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, single-dose preparations with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test A (compressed and moulded dosage forms) or test B (capsules) for the uniformity of content of single-dose preparations. If the preparation contains more than one active substance, this requirement applies only to those substances that correspond to the above conditions.

Uniformity of mass (2.9.5). Solid single-dose preparations comply with the test for uniformity of mass. If the test for the uniformity of content is prescribed, or justified and authorised for all active substances, the test for uniformity of mass is not required.

LABELLING

The label states the name of any added antimicrobial preservative.

Gargles

DEFINITION

Gargles are aqueous solutions intended for gargling to obtain a local effect. They are not to be swallowed. They are supplied as ready-to-use solutions or concentrated solutions to be diluted. They may also be prepared from powders or tablets to be dissolved in water before use.

Gargles may contain excipients to adjust the pH which, as far as possible, is neutral.

Mouthwashes

DEFINITION

Mouthwashes are aqueous solutions intended for use in contact with the mucous membrane of the oral cavity, usually after dilution with water. They are not to be swallowed.

They are supplied as ready-to-use solutions or concentrated solutions to be diluted. They may also be prepared from powders or tablets to be dissolved in water before use.

Mouthwashes may contain excipients to adjust the pH which, as far as possible, is neutral.

Gingival solutions

DEFINITION

Gingival solutions are intended for administration to the gingivae by means of a suitable applicator.

Oromucosal solutions and oromucosal suspensions

DEFINITION

Oromucosal solutions and oromucosal suspensions are liquid preparations intended for administration to the oral cavity by means of a suitable applicator.

Oromucosal suspensions may show a sediment which is readily dispersible on shaking to give a suspension which remains sufficiently stable to enable the correct dose to be delivered.

Semi-solid oromucosal preparations

DEFINITION

Semi-solid oromucosal preparations are hydrophilic gels or pastes intended for administration to the oral cavity or to a specific part of the oral cavity such as the gingivae (gingival gel, gingival paste). They may be provided as single-dose preparations.

Semi-solid oromucosal preparations comply with the requirements of the monograph on *Semi-solid preparations for cutaneous use (0132)*.

Oromucosal drops, oromucosal sprays and sublingual sprays

DEFINITION

Oromucosal drops, oromucosal sprays and sublingual sprays are solutions, emulsions or suspensions intended for local or systemic effect. They are applied by instillation or spraying into the oral cavity or onto a specific part of the oral cavity such as spraying under the tongue (sublingual spray) or into the throat (oropharyngeal spray).

Emulsions may show evidence of phase separation but are readily redispersed on shaking. Suspensions may show a sediment which is readily dispersed on shaking to give a suspension which remains sufficiently stable to enable the correct dose to be delivered.

Liquid oromucosal sprays are supplied in containers with atomising devices or in pressurised containers having a suitable adaptor, with or without a metering dose valve, which comply with the requirements of the monograph on *Pressurised pharmaceutical preparations (0523)*.

The size of the droplets of the spray is such as to localise their deposition in the oral cavity or the throat as intended.

TESTS

Unless otherwise prescribed or justified and authorised, oromucosal drops supplied in single-dose containers, single-doses of metered oromucosal sprays and sublingual sprays intended for systemic action comply with the following tests.

Uniformity of mass. Oromucosal drops that are solutions comply with the following test: determine the individual masses of the contents of 10 containers emptied as completely as possible, and calculate the average mass. Not more than 2 of the individual masses deviate by more than 10 per cent from the average mass and none deviates by more than 20 per cent.

Metered-dose oromucosal sprays and sublingual sprays that are solutions comply with the following test: discharge once to waste. Wait for not less than 5 s and discharge again to waste. Repeat this procedure for a further 3 actuations. Weigh the mass of the container, discharge once to waste and weigh the remaining mass of the container. Calculate the difference between the 2 masses. Repeat the procedure for a further 9 containers. The preparation complies with the test if not more than 2 of the individual masses deviate by more than 25 per cent from the average value and none deviates by more than 35 per cent.

Uniformity of content (2.9.6). Oromucosal drops that are suspensions or emulsions comply with the following test: empty each container as completely as possible and carry out the test on the individual contents. They comply with test B of uniformity of content.

Uniformity of delivered dose. Metered-dose oromucosal sprays and sublingual sprays that are suspensions or emulsions comply with the following test: use an apparatus capable of quantitatively retaining the dose leaving the actuator of the atomising device.

Shake a container for 5 s and discharge once to waste. Wait for not less than 5 s, shake for 5 s and discharge again to waste. Repeat this procedure for a further 3 actuations. After 2 s, fire one dose of the metered-dose oromucosal spray into the collecting vessel by actuating the atomising device. Collect the contents of the collecting vessel by successive rinses. Determine the content of active substance in the combined rinses. Repeat the procedure for a further 9 containers. Unless otherwise justified and authorised, the preparation complies with the test if not more than one of the individual contents is outside the limits of 75 per cent to 125 per cent and none is outside the limits of 65 per cent to 135 per cent of the average content.

If 2 or 3 individual contents are outside the limits of 75 per cent to 125 per cent but within the limits of 65 per cent to 135 per cent, repeat the test for 20 more containers. The preparation complies with the test if not more than 3 individual contents of the 30 contents are outside the limits of 75 per cent to 125 per cent and none is outside the limits of 65 per cent to 135 per cent of the average content.

Lozenges and pastilles

DEFINITION

Lozenges and pastilles are solid, single-dose preparations intended to be sucked to obtain, usually, a local effect in the oral cavity and the throat. They contain one or more active substances, usually in a flavoured and sweetened base, and are intended to dissolve or disintegrate slowly in the mouth when sucked.

Lozenges are hard preparations prepared by moulding. Pastilles are soft, flexible preparations prepared by moulding of mixtures containing natural or synthetic polymers or gums and sweeteners.

Compressed lozenges

DEFINITION

Compressed lozenges are solid, single-dose preparations intended to be sucked to obtain a local or systemic effect. They are prepared by compression and are often rhomboid in shape.

Compressed lozenges conform with the general definition of tablets.

PRODUCTION

In the manufacture of compressed lozenges, means are taken to ensure that they possess a suitable mechanical strength to resist handling without crumbling or breaking. This may be demonstrated by examining the *Friability of uncoated tablets (2.9.7)* and the *Resistance to crushing of tablets (2.9.8)*.

TESTS

Dissolution. For compressed lozenges intended for a systemic effect, a suitable test is carried out to demonstrate the appropriate release of the active substance(s).

Sublingual tablets and buccal tablets

DEFINITION

Sublingual tablets and buccal tablets are solid, single-dose preparations to be applied under the tongue or to the buccal cavity, respectively, to obtain a systemic effect. They are prepared by compression of mixtures of powders or granulations into tablets with a shape suited for the intended use.

Sublingual tablets and buccal tablets conform to the general definition of tablets.

PRODUCTION

In the manufacture of sublingual tablets and buccal tablets, means are taken to ensure that they possess suitable mechanical strength to resist handling without crumbling or breaking. This may be demonstrated by examining the *Friability of uncoated tablets (2.9.7)* and the *Resistance to crushing of tablets (2.9.8)*.

TESTS

Dissolution. Unless otherwise justified and authorised, a suitable test is carried out to demonstrate the appropriate release of the active substance(s).

Oromucosal capsules

DEFINITION

Oromucosal capsules are soft capsules to be chewed or sucked.

Mucoadhesive preparations

DEFINITION

Mucoadhesive preparations contain one or more active substances intended for systemic absorption through the buccal mucosa over a prolonged period of time. They may be supplied as mucoadhesive buccal tablets or as other mucoadhesive solid or semi-solid preparations.

Mucoadhesive buccal tablets are prepared by compression of mono- or multi-layered tablets. They usually contain hydrophilic polymers, which on wetting with the saliva produce a flexible hydrogel that adheres to the buccal mucosa.

PRODUCTION

In the manufacture of mucoadhesive buccal tablets, means are taken to ensure that they possess suitable mechanical strength to resist handling without crumbling or breaking. This may be demonstrated by examining the *Friability of uncoated tablets* (2.9.7) and the *Resistance to crushing of tablets* (2.9.8).

TESTS

Dissolution. Unless otherwise justified and authorised, a suitable test is carried out to demonstrate the appropriate release of the active substance(s).

01/2005:0520

PARENTERAL PREPARATIONS

Parenteralia

The requirements of this monograph do not necessarily apply to products derived from human blood, to immunological preparations, or radiopharmaceutical preparations. Special requirements may apply to preparations for veterinary use depending on the species of animal for which the preparation is intended.

DEFINITION

Parenteral preparations are sterile preparations intended for administration by injection, infusion or implantation into the human or animal body.

Parenteral preparations may require the use of excipients, for example to make the preparation isotonic with blood, to adjust the pH, to increase solubility, to prevent deterioration of the active substances or to provide adequate antimicrobial properties but not to adversely affect the intended medicinal action of the preparation or, at the concentrations used, to cause toxicity or undue local irritation.

Containers for parenteral preparations are made as far as possible from materials that are sufficiently transparent to permit the visual inspection of the contents, except for implants and in other justified and authorised cases.

Where applicable, the containers for parenteral preparations comply with the requirements for *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

Parenteral preparations are supplied in glass containers (3.2.1) or in other containers such as plastic containers (3.2.2, 3.2.2.1 and 3.2.9) and prefilled syringes. The tightness of the container is ensured by suitable means. Closures ensure a good seal, prevent the access of micro-organisms and other contaminants and usually permit the withdrawal of a part or the whole of the contents without removal of the closure. The plastic materials or elastomers (3.2.9) of which the closure is composed are sufficiently firm and elastic to allow the passage of a needle with the least possible shedding of particles. Closures for multidose containers are sufficiently elastic to ensure that the puncture is resealed when the needle is withdrawn.

Several categories of parenteral preparations may be distinguished:

- injections,
- infusions,
- concentrates for injections or infusions,
- powders for injections or infusions,
- implants.

PRODUCTION

During the development of a parenteral preparation, the formulation for which contains an antimicrobial preservative, the effectiveness of the chosen preservative shall be demonstrated to the satisfaction of the competent authority. A suitable test method together with criteria for judging the preservative properties of the formulation are provided under *Efficacy of antimicrobial preservation* (5.1.3).

Parenteral preparations are prepared using materials and methods designed to ensure sterility and to avoid the introduction of contaminants and the growth of micro-organisms; recommendations on this aspect are provided in the text on *Methods of preparation of sterile products* (5.1.1).

Water used in the manufacture of parenteral preparations complies with the requirements of water for injections in bulk stated in the monograph on *Water for injections* (0169).

TESTS

Particulate contamination: sub-visible particles (2.9.19).

For preparations for human use, solutions for infusion or solutions for injection supplied in containers with a nominal content of more than 100 ml comply with the test.

For preparations for veterinary use, when supplied in containers with a nominal content of more than 100 ml and when the content is equivalent to a dose of more than 1.4 ml per kilogram of body mass, solutions for infusion or solutions for injection comply with the test for particulate contamination: sub-visible particles.

Products for which the label states that the product is to be used with a final filter are exempt from these requirements.

Sterility (2.6.1). Parenteral preparations comply with the test for sterility.

STORAGE

Store in a sterile, airtight, tamper-proof container.

LABELLING

The label states:

- the name and concentration of any added antimicrobial preservative,
- where applicable, that the solution is to be used in conjunction with a final filter,
- where applicable, that the preparation is free from bacterial endotoxins or that it is apyrogenic.

Injections

DEFINITION

Injections are sterile solutions, emulsions or suspensions. They are prepared by dissolving, emulsifying or suspending the active substance(s) and any added excipients in *Water for injections* (0169), in a suitable, sterile non-aqueous liquid or in a mixture of these vehicles.

Solutions for injection, examined under suitable conditions of visibility, are clear and practically free from particles.

Emulsions for injection do not show any evidence of phase separation. Suspensions for injection may show a sediment which is readily dispersed on shaking to give a suspension which remains sufficiently stable to enable the correct dose to be withdrawn.

Multidose preparations. Multidose aqueous injections contain a suitable antimicrobial preservative at an appropriate concentration except when the preparation itself has adequate antimicrobial properties. When it is necessary to present a preparation for parenteral use in a multidose

container, the precautions to be taken for its administration and more particularly for its storage between successive withdrawals are given.

Antimicrobial preservatives. Aqueous preparations which are prepared using aseptic precautions and which cannot be terminally sterilised may contain a suitable antimicrobial preservative in an appropriate concentration.

No antimicrobial preservative is added when:

- the volume to be injected in a single dose exceeds 15 ml, unless otherwise justified,
- the preparation is intended for administration by routes where, for medical reasons, an antimicrobial preservative is not acceptable, such as intracisternally, epidurally, intrathecally or by any route giving access to the cerebrospinal fluid, or intra- or retro-ocularly.

Such preparations are presented in single-dose containers.

PRODUCTION

In the manufacture of injections containing dispersed particles, measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

Single-dose preparations. The volume of the injection in a single-dose container is sufficient to permit the withdrawal and administration of the nominal dose using a normal technique.

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, single-dose suspensions for injection with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test A for uniformity of content of single-dose preparations. If the preparation contains more than one active substance, the requirement applies only to those substances that correspond to the above conditions.

Bacterial endotoxins - pyrogens. A test for bacterial endotoxins (2.6.14) is carried out or, where justified and authorised, the test for pyrogens (2.6.8). Recommendations on the limits for bacterial endotoxins are given in chapter 2.6.14.

Preparations for human use. The preparation complies with a test for bacterial endotoxins (2.6.14) or with the test for pyrogens (2.6.8).

Preparations for veterinary use. When the volume to be injected in a single dose is 15 ml or more and is equivalent to a dose of 0.2 ml or more per kilogram of body mass, the preparation complies with a test for bacterial endotoxins (2.6.14) or with the test for pyrogens (2.6.8).

Any preparation. Where the label states that the preparation is free from bacterial endotoxins or apyrogenic, respectively, the preparation complies with a test for bacterial endotoxins (2.6.14) or with the test for pyrogens (2.6.8), respectively.

Infusions

DEFINITION

Infusions are sterile, aqueous solutions or emulsions with water as the continuous phase; they are usually made isotonic with blood. They are principally intended for administration in large volume. Infusions do not contain any added antimicrobial preservative.

Solutions for infusion, examined under suitable conditions of visibility, are clear and practically free from particles.

Emulsions for infusion do not show any evidence of phase separation.

PRODUCTION

In the manufacture of infusions containing dispersed particles, measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

The volume of the infusion in the container is sufficient to permit the withdrawal and administration of the nominal dose using a normal technique (2.9.17).

TESTS

Bacterial endotoxins - pyrogens. They comply with a test for bacterial endotoxins (2.6.14) or, where justified and authorised, with the test for pyrogens (2.6.8). For the latter test, inject 10 ml per kilogram of body mass into each rabbit, unless otherwise justified and authorised.

Concentrates for injections or infusions

DEFINITION

Concentrates for injections or infusions are sterile solutions intended for injection or infusion after dilution. They are diluted to a prescribed volume with a prescribed liquid before administration. After dilution, they comply with the requirements for injections or for infusions.

TESTS

Bacterial endotoxins - pyrogens. They comply with the requirements prescribed for injections or for infusions, after dilution to a suitable volume.

Powders for injections or infusions

DEFINITION

Powders for injections or infusions are solid, sterile substances distributed in their final containers and which, when shaken with the prescribed volume of a prescribed sterile liquid, rapidly form either clear and practically particle-free solutions or uniform suspensions. After dissolution or suspension, they comply with the requirements for injections or for infusions.

Freeze-dried products for parenteral use are considered as powders for injections or infusions.

PRODUCTION

The uniformity of content and uniformity of mass of freeze-dried products for parenteral use are ensured by the in-process control of the amount of the solution prior to freeze-drying.

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, powders for injections or infusions with a content of active substance less than 2 mg or less than 2 per cent of the total mass or with a unit mass equal to or less than 40 mg comply with test A for uniformity of content of single-dose preparations. If the preparation contains more than one active substance, the requirement applies only to those substances that correspond to the above conditions.

Uniformity of mass (2.9.5). Powders for injections or infusions comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

Bacterial endotoxins - pyrogens. They comply with the requirements prescribed for injections or for infusions, after dissolution or suspension in a suitable volume of liquid.

LABELLING

The label states the instructions for the preparation of injections and infusions.

Implants

DEFINITION

Implants are sterile, solid preparations of a size and shape suitable for parenteral implantation and release the active substance(s) over an extended period of time. Each dose is provided in a sterile container.

01/2005:1011

PATCHES, TRANSDERMAL

Emplastra transcutanea

DEFINITION

Transdermal patches are flexible pharmaceutical preparations of varying sizes, containing one or more active substances. They are intended to be applied to the unbroken skin in order to deliver the active substance(s) to the systemic circulation after passing through the skin barrier.

Transdermal patches normally consist of an outer covering which supports a preparation which contains the active substance(s). The transdermal patches are covered on the site of the release surface of the preparation by a protective liner, which is removed before applying the patch to the skin.

The outer covering is a backing sheet impermeable to the active substance(s) and normally impermeable to water, designed to support and protect the preparation. The outer covering may have the same dimensions as the preparation or it may be larger. In the latter case the overlapping border of the outer covering is covered by pressure-sensitive adhesive substances which assure the adhesion of the patch to the skin.

The preparation contains the active substance(s) together with excipients such as stabilisers, solubilisers or substances intended to modify the release rate or to enhance transdermal absorption. It may be a single layer or multi-layer solid or semi-solid matrix, and in this case it is the composition and structure of the matrix which determines the diffusion pattern of the active substance(s) to the skin. The matrix may contain pressure-sensitive adhesives which assure the adhesion of the preparation to the skin. The preparation may exist as a semi-solid reservoir one side of which is a membrane which may control the release and the diffusion of the active substance(s) from the preparation. The pressure-sensitive adhesive substances may, in this case, be applied to some or all parts of the membrane, or only around the border of the membrane of the outer covering.

When applied to the dried, clean and unbroken skin, the transdermal patch adheres firmly to the skin by gentle pressure of the hand or the fingers and can be peeled off without causing appreciable injury to the skin or detachment of the preparation from the outer covering. The patch must not be irritant or sensitising to the skin, even after repeated applications.

The protective liner generally consists of a sheet of plastic or metal material. When removed, the protective liner does not detach the preparation (matrix or reservoir) or the adhesive from the patch.

Transdermal patches are normally individually enclosed in sealed sachets.

PRODUCTION

In the manufacture, packaging, storage and distribution of transdermal patches suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, transdermal patches comply with test C for uniformity of content of single-dose preparations.

Dissolution. A suitable test may be required to demonstrate the appropriate release of the active substance(s), for example one of the tests described in *Dissolution test for transdermal patches* (2.9.4). The disc assembly method, the cell method or the rotating cylinder method may be used, as suitable, according to the composition, dimensions and shape of the patch.

A membrane may be used. It can be of various materials, such as inert porous cellulose or silicones, and must not affect the release kinetics of the active substance(s) from the patch. Furthermore, it must be free of substances that may interfere with its performance (for example grease). The membrane may be suitably treated before the tests, for example, by maintaining it in the medium to be used in the test for 24 h. Apply the membrane above the releasing surface of the patch, avoiding the formation of air bubbles. The test conditions and the requirements are to be authorised by the competent authority.

STORAGE

Store at room temperature, unless otherwise indicated.

LABELLING

The label states, where applicable, the total quantity of active substance(s) per patch, the dose released per unit time and the area of the releasing surface.

01/2005:1166

POWDERS FOR CUTANEOUS APPLICATION

Pulveres ad usum dermicum

Where justified and authorised, the requirements of this monograph do not apply to powders for cutaneous application intended for veterinary use.

DEFINITION

Powders for cutaneous application are preparations consisting of solid, loose, dry particles of varying degrees of fineness. They contain one or more active substances, with or without excipients and, if necessary, colouring matter authorised by the competent authority.

Powders for cutaneous application are presented as single-dose powders or multidose powders. They are free from grittiness. Powders specifically intended for use on large open wounds or on severely injured skin are sterile.

Multidose powders for cutaneous application may be dispensed in sifter-top containers, containers equipped with a mechanical spraying device or in pressurised containers.

Powders dispensed in pressurised containers comply with the requirements of *Pressurised pharmaceutical preparations* (0523).

Where applicable, containers for powders comply with the requirements of *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

PRODUCTION

In the manufacture of powders for cutaneous application, measures are taken to ensure a suitable particle size with regard to the intended use.

In the manufacture, packaging, storage and distribution of powders for cutaneous application, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

Sterile powders for cutaneous application are prepared using materials and methods designed to ensure sterility and to avoid the introduction of contaminants and the growth of micro-organisms; recommendations on this aspect are provided in the text on *Methods of preparation of sterile products* (5.1.1).

TESTS

Fineness. If prescribed, the fineness of a powder is determined by the sieve test (2.9.12) or another appropriate method.

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, single-dose powders for cutaneous application with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test B for uniformity of content of single-dose preparations. If the preparation has more than one active substance, the requirement applies only to those substances which correspond to the above conditions.

Uniformity of mass (2.9.5). Single-dose powders for cutaneous application comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

Sterility (2.6.1). Where the label indicates that the preparation is sterile, it complies with the test for sterility.

LABELLING

The label states:

- that the preparation is for external use,
- where applicable, that the preparation is sterile.

01/2005:1165

POWDERS, ORAL

Pulveres perorales

Requirements for powders to be used for the preparation of oral solutions or suspensions are given in the monograph for Liquid preparations for oral use (0672). Where justified and authorised, the requirements of this monograph do not apply to oral powders intended for veterinary use.

DEFINITION

Oral powders are preparations consisting of solid, loose, dry particles of varying degrees of fineness. They contain one or more active substances, with or without excipients and, if necessary, colouring matter authorised by the competent authority and flavouring substances. They are generally administered in or with water or another suitable liquid. They may also be swallowed directly. They are presented as single-dose or multidose preparations.

Where applicable, containers for oral powders comply with the requirements of *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

Multidose oral powders require the provision of a measuring device capable of delivering the quantity prescribed. Each dose of a single-dose powder is enclosed in an individual container, for example a sachet or a vial.

PRODUCTION

In the manufacture of oral powders, means are taken to ensure a suitable particle size with regard to the intended use.

In the manufacture, packaging, storage and distribution of oral powders, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, single-dose oral powders with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test B for uniformity of content of single-dose preparations. If the preparation has more than one active substance, the requirement applies only to those substances which correspond to the above conditions.

Uniformity of mass (2.9.5). Single-dose oral powders comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

Uniformity of mass of delivered doses from multidose containers (2.9.27). Oral powders supplied in multidose containers comply with the test.

STORAGE

If the preparation contains volatile ingredients, or the contents have to be protected, store in an airtight container.

Effervescent powders

Effervescent powders are presented as single-dose or multidose preparations and generally contain acid substances and carbonates or hydrogen carbonates which react rapidly in the presence of water to release carbon dioxide. They are intended to be dissolved or dispersed in water before administration.

STORAGE

In an airtight container.

01/2005:1037

PREMIXES FOR MEDICATED FEEDING STUFFS FOR VETERINARY USE

Praeadmixta ad alimenta medicata ad usum veterinarium

DEFINITION

Mixtures of one or more active substances, usually in suitable bases, that are prepared to facilitate feeding the active substances to animals. They are used exclusively in the preparation of medicated feeding stuffs.

Premixes occur in granulated, powdered, semi-solid or liquid form. Used as powders or granules, they are free-flowing and homogeneous; any aggregates break apart during normal handling. Used in liquid form, they are homogeneous suspensions or solutions which may be obtained from thixotropic gels or structured liquids. The particle size and other properties are such as to ensure uniform distribution of the active substance(s) in the final feed. Unless otherwise justified and authorised, the instructions for use state that the concentration of a premix in granulated or powdered form is at least 0.5 per cent in the medicated feeding stuff.

PRODUCTION

Active substance. An active substance intended for incorporation into a medicated premix complies with the requirements of the relevant monograph of the European Pharmacopoeia, unless already otherwise justified and authorised for existing premixes.

TESTS

Loss on drying (2.2.32). Unless otherwise justified and authorised, for premixes occurring in granulated or powdered form, maximum 15.0 per cent, determined on 3.000 g by drying in an oven at 100-105 °C for 2 h.

LABELLING

The label states:

- the category of animal for which the premix is intended,
- the instructions for the preparation of the medicated feeding stuffs from the premix and the basic feed,
- where applicable, the time that must elapse between the cessation of feeding of the medicated feeding stuff and collection of the material intended for human consumption.

PRODUCTION

During the development of a preparation for inhalation which contains an antimicrobial preservative, the effectiveness of the chosen preservative shall be demonstrated to the satisfaction of the competent authority. A suitable test method together with the criteria for judging the preservative properties of the formulation are described in the text on *Efficacy of antimicrobial preservation (5.1.3)*.

The size of aerosol particles to be inhaled is controlled so that a significant fraction is deposited in the lung. The fine-particle characteristics of preparations for inhalation are determined by the method for *Aerodynamic assessment of fine particles (2.9.18)*.

In assessing the uniformity of delivered dose of a multidose inhaler, it is not sufficient to test a single inhaler.

Manufacturers must substitute procedures which take both inter- and intra-inhaler dose uniformity into account. A suitable procedure based on the intra-inhaler test would be to collect each of the specified doses at the beginning, middle and end of the number of doses stated on the label from separate inhalers.

Pressurised metered-dose inhalers are tested for leakage. All inhalers are tested for extraneous particulate contamination.

LABELLING

For metered-dose preparations the label states:

- the delivered dose, except for preparations for which the dose has been established as a metered-dose or as a predisposed-dose,
- where applicable, the number of deliveries from the inhaler to provide the minimum recommended dose,
- the number of deliveries per inhaler.

The label states, where applicable, the name of any added antimicrobial preservative.

Liquid preparations for inhalation

Three categories of liquid preparations for inhalation may be distinguished:

- A. preparations intended to be converted into vapour,
- B. liquid preparations for nebulisation,
- C. pressurised metered-dose preparations for inhalation.

Liquid preparations for inhalation are solutions or dispersions.

Dispersions are readily dispersible on shaking and they remain sufficiently stable to enable the correct dose to be delivered. Suitable excipients may be used.

A. PREPARATIONS INTENDED TO BE CONVERTED INTO VAPOUR

DEFINITION

Preparations intended to be converted into vapour are solutions, dispersions or solid preparations. They are usually added to hot water and the vapour generated is inhaled.

B. LIQUID PREPARATIONS FOR NEBULISATION

DEFINITION

Liquid preparations for inhalation intended to be converted into aerosols by continuously operating nebulisers or metered-dose nebulisers are solutions, suspensions or emulsions. Suitable co-solvents or solubilisers may be used to increase the solubility of the active substances.

Liquid preparations for nebulisation in concentrated form for use in continuously operating nebulisers are diluted to the prescribed volume with the prescribed liquid before use. Liquids for nebulisation may also be prepared from powders.

01/2005:0671

PREPARATIONS FOR INHALATION

Inhalanda

DEFINITION

Preparations for inhalation are liquid or solid preparations intended for administration as vapours or aerosols to the lung in order to obtain a local or systemic effect. They contain one or more active substances which may be dissolved or dispersed in a suitable vehicle.

Preparations for inhalation may, depending on the type of preparation, contain propellants, co-solvents, diluents, antimicrobial preservatives, solubilising and stabilising agents, etc. These excipients do not adversely affect the functions of the mucosa of the respiratory tract or its cilia.

Preparations for inhalation are supplied in multidose or single-dose containers. When supplied in pressurised containers, they comply with the requirements of the monograph on *Pressurised pharmaceutical preparations (0523)*.

Preparations intended to be administered as aerosols (dispersions of solid or liquid particles in a gas) are administered by one of the following devices:

- nebuliser,
- pressurised metered-dose inhaler,
- dry-powder inhaler.

The pH of the liquid preparations for use in continuously operating nebulisers is not lower than 3 and not higher than 8.5.

Suspensions and emulsions are readily dispersible on shaking and they remain sufficiently stable to enable the correct dose to be delivered.

Aqueous preparations for nebulisation supplied in multidose containers may contain a suitable antimicrobial preservative at a suitable concentration except where the preparation itself has adequate antimicrobial properties.

Continuously operating nebulisers are devices that convert liquids into aerosols by high-pressure gases, ultrasonic vibration or other methods. They allow the dose to be inhaled at an appropriate rate and particle size which ensures deposition of the preparation in the lungs.

Metered-dose nebulisers are devices that convert liquids into aerosols by high-pressure gases, ultrasonic vibration or other methods. The volume of liquid to be nebulised is metered so that the aerosol dose can be inhaled with one breath.

C. PRESSURISED METERED-DOSE PREPARATIONS FOR INHALATION

DEFINITION

Pressurised metered-dose preparations for inhalation are solutions, suspensions or emulsions supplied in special containers equipped with a metering valve and which are held under pressure with suitable propellants or suitable mixtures of liquefied propellants, which can act also as solvents. Suitable co-solvents, solubilisers and stabilisers may be added.

The delivered dose is the dose delivered from the inhaler to the patient. For some preparations, the dose has been established as a metered-dose. The metered-dose is determined by adding the amount deposited within the device to the delivered dose. It may also be determined directly.

TESTS

Uniformity of delivered dose. Containers usually operate in an inverted position. For containers that operate in an upright position, an equivalent test is applied using methods that ensure the complete collection of the delivered dose. In all cases, prepare the inhaler as directed in the instructions to the patient.

The dose collection apparatus must be capable of quantitatively capturing the delivered dose.

The following apparatus and procedure may be used.

The apparatus (Figure 0671.-1) consists of a filter-support base with an open-mesh filter-support, such as a stainless steel screen, a collection tube that is clamped or screwed to the filter-support base, and a mouthpiece adapter to ensure an airtight seal between the collection tube and the mouthpiece. Use a mouthpiece adapter which ensures that the front face of the inhaler mouthpiece is flush with the front face of the sample collection tube. The vacuum connector is connected to a system comprising a vacuum source and a flow regulator. The source should be adjusted to draw air through the complete assembly, including the filter and the inhaler to be tested, at 28.3 ± 1.5 litres/min. Air should be drawn continuously through the apparatus to avoid loss of the active substance into the atmosphere. The filter support base is designed to accommodate 25 mm diameter filter disks. The filter disk and other materials used in the construction of the apparatus must be compatible with the active substance and solvents that are used to extract the active substance from the filter. One end of the collection tube is designed to hold the filter disk tightly against the filter-support base. When assembled, the joints between the

components of the apparatus are airtight so that when a vacuum is applied to the base of the filter, all of the air drawn through the collection tube passes through the inhaler.

Unless otherwise prescribed in the instructions to the patient, shake the inhaler for 5 s and discharge one delivery to waste. Fire the inverted inhaler into the apparatus, depressing the valve for a sufficient time to ensure complete discharge. Repeat the procedure until the number of deliveries that constitute the minimum recommended dose have been sampled. Quantitatively collect the contents of the apparatus and determine the amount of active substance.

Repeat the procedure for a further 2 doses.

Discharge the device to waste, waiting not less than 5 s between actuations until $(n/2)+1$ deliveries remain, where n is the number of deliveries stated on the label. Collect 4 doses using the procedure described above.

Discharge the device to waste, waiting not less than 5 s between actuations until 3 doses remain. Collect these 3 doses using the procedure described above.

For preparations containing more than one active substance, carry out the test for uniformity of delivered dose for each active substance.

Unless otherwise justified and authorised, the preparation complies with the test if 9 out of 10 results lie between 75 per cent and 125 per cent of the average value and all lie between 65 per cent and 135 per cent. If 2 or 3 values lie outside the range of 75 per cent to 125 per cent, repeat the test for 2 more inhalers. Not more than 3 of the 30 values lie outside the range 75 per cent to 125 per cent and no value lies outside the range 65 per cent to 135 per cent.

Fine particle dose. Using an apparatus and procedure described in *Aerodynamic assessment of fine particles (2.9.18 - apparatus C or D)*, calculate the fine particle dose.

Number of deliveries per inhaler. Take one inhaler and discharge the contents to waste, actuating the valve at intervals of not less than 5 s. The total number of deliveries so discharged from the inhaler is not less than the number stated on the label (this test may be combined with the test for uniformity of delivered dose).

Powders for inhalation

DEFINITION

Powders for inhalation are presented as single-dose powders or multidose powders. To facilitate their use, active substances may be combined with a suitable carrier. They are generally administered by dry-powder inhalers. In pre-metered systems, the inhaler is loaded with powders pre-dispensed in capsules or other suitable pharmaceutical forms. For devices using a powder reservoir, the dose is created by a metering mechanism within the inhaler.

The delivered dose is the dose delivered from the inhaler. For some preparations, the dose has been established as a metered dose or as a predispensed dose. The metered dose is determined by adding the amount deposited within the device to the delivered dose. It may also be determined directly.

TESTS

Uniformity of delivered dose. In all cases, prepare the inhaler as directed in the instructions to the patient. The dose collection apparatus must be capable of quantitatively capturing the delivered dose. A dose collection apparatus similar to that described for the evaluation of pressurised metered-dose inhalers may be used provided that the dimensions of the tube and the filter can accommodate

Figure 0671-1. – Dose collection apparatus for pressurised metered-dose preparations
Dimensions in millimetres

the measured flow rate. A suitable tube is defined in Figure 0671-1. Connect the tube to a flow system according to the scheme specified in Figure 0671-2 and Table 0671-1.

Unless otherwise stated, determine the test flow rate and duration using the dose collection tube, the associated flow system, a suitable differential pressure meter and a suitable volumetric flow meter, calibrated for the flow leaving the meter, according to the following procedure.

Prepare the inhaler for use and connect it to the inlet of the apparatus using a mouthpiece adapter to ensure an airtight seal. Use a mouthpiece adapter which ensures that the front face of the inhaler mouthpiece is flush with the front face of the sample collection tube. Connect one port of a differential pressure meter to the pressure reading point, P1, in Figure 0671-2 and let the other be open to the

atmosphere. Switch on the pump, open the two way valve and adjust the flow control valve until the pressure drop across the inhaler is 4.0 kPa (40.8 cm H₂O) as indicated by the differential pressure meter. Remove the inhaler from the mouthpiece adapter and without touching the flow control valve, connect a flow meter to the inlet of the sampling apparatus. If the flow rate is above 100 litres/min adjust the flow control valve to obtain a flow rate of 100 ± 5 litres/min. Note the volumetric airflow rate and define this as the test flow rate, Q, in litres per minute. Define the test flow duration, T, in seconds so that a volume of 4 litres of air is drawn through the inhaler.

Ensure that critical flow occurs in the flow control valve by the following procedure. With the inhaler in place and the test flow rate Q, measure the absolute pressure on both sides of the control valve (pressure reading points P2 and P3 in

Figure 0671.2). A ratio $P3/P2 \leq 0.5$ indicates critical flow. Switch to a more powerful pump and re-measure the test flow rate if critical flow is not indicated.

Predispensed systems. Prepare the inhaler as directed in the instructions to the patient and connect it to the apparatus using an adapter which ensures a good seal. Draw air through the inhaler using the predetermined conditions. Repeat the procedure until the number of deliveries which constitute the minimum recommended dose have been sampled. Quantitatively collect the contents of the apparatus and determine the amount of active substance.

Repeat the procedure for a further 9 doses.

Reservoir systems. Prepare the inhaler as directed in the instructions to the patient and connect it to the apparatus using an adapter which ensures a good seal. Draw air through the inhaler under the predetermined conditions. Repeat the procedure until the number of deliveries which constitute the minimum recommended dose have been sampled. Quantitatively collect the contents of the apparatus and determine the amount of active substance.

Repeat the procedure for a further 2 doses.

Discharge the device to waste until $(n/2)+1$ deliveries remain, where n is the number of deliveries stated on the label. If necessary, store the inhaler to discharge electrostatic charges. Collect 4 doses using the procedure described above.

Discharge the device to waste until 3 doses remain. If necessary, store the inhaler to discharge electrostatic charges. Collect 3 doses using the procedure described above.

For preparations containing more than 1 active substance, carry out the test for uniformity of delivered dose for each active substance.

The preparation complies with the test if 9 out of 10 results lie between 75 per cent and 125 per cent of the average value and all lie between 65 per cent and 135 per cent. If 2 or 3 values lie outside the range of 75 per cent to 125 per cent, repeat the test for 2 more inhalers. Not more than 3 of the 30 values lie outside the range 75 per cent to 125 per cent and no value lies outside the range 65 per cent to 135 per cent.

In justified and authorised cases, these ranges may be extended but no value should be greater than 150 per cent or less than 50 per cent of the average value.

Table 0671.1. – Specifications of the apparatus described in figure 0671.2

Code	Item	Description
A	Sample collection tube	Capable of quantitatively capturing the delivered dose, e.g. Dose collection tube similar to that described in Fig. 0671.1 with dimensions of 34.85 mm ID × 12 cm length (e.g. product number XX40 047 00, Millipore Corporation, Bedford, MA 01732 with modified exit tube, ID ≥ 8 mm, fitted with Gelman product number 61631), or equivalent.
B	Filter	47 mm filter, e.g. A/E glass fibre filter (Gelman Sciences, Ann Arbor, MI 48106), or equivalent.
C	Connector	ID ≥ 8 mm, e.g., short metal coupling, with low-diameter branch to P3.
D	Vacuum tubing	8 ± 0.5 mm ID × 50 ± 10 cm length, e.g., silicone tubing with an OD of 14 mm and an ID of 8 mm.
E	Two-way solenoid valve	Minimum airflow resistance orifice having an ID of ≥ 8 mm and a maximum response time of 100 ms (e.g. type 256-A08, Bürkert GmbH, D-74653 Ingelfingen), or equivalent.
F	Vacuum pump	Pump must be capable of drawing the required flow rate through the assembled apparatus with the dry powder inhaler in the mouthpiece adapter (e.g. product type 1023, 1423 or 2565, Gast Manufacturing Inc., Benton Harbor, MI 49022), or equivalent. Connect the pump to the solenoid valve using short and/or wide (≥ 10 mm ID) vacuum tubing and connectors to minimise pump capacity requirements.
G	Timer	Timer capable of driving the solenoid valve for the required time period (e.g. type G814, RS Components International, Corby, NN17 9RS, UK), or equivalent.
P1	Pressure tap	2.2 mm ID, 3.1 mm OD, flush with internal surface of the sample collection tube, centred and burr-free, 59 mm from its inlet.
P1 P2 P3	Pressure measurements	Differential pressure to atmosphere (P1) or absolute pressure (P2 and P3).
H	Flow control valve	Adjustable regulating valve with maximum $C_v \geq 1$, (e.g. type 8FV12LNSS, Parker Hannifin plc., Barnstaple, EX31 1NP, UK), or equivalent.

Fine particle dose. Using the apparatus and procedure described in *Aerodynamic assessment of fine particles (2.9.18 - apparatus C or D)*, calculate the fine particle dose.

Number of deliveries per inhaler for multidose inhalers. Discharge doses from the inhaler until empty, at the predetermined flow rate. Record the deliveries discharged.

Figure 0671.2. – Apparatus suitable for measuring the uniformity of delivered dose for powder inhalers

The total number of doses delivered is not less than the number stated on the label (this test may be combined with the test for uniformity of delivered dose).

01/2005:0523

PRESSURISED PHARMACEUTICAL PREPARATIONS

01/2005:1116

Praeparationes pharmaceuticae in vasis cum pressu

PREPARATIONS FOR IRRIGATION

Praeparationes ad irrigationem

DEFINITION

Preparations for irrigation are sterile, aqueous large volume preparations intended to be used for irrigation of body cavities, wounds and surfaces, for example during surgical procedures.

Preparations for irrigation are either solutions prepared by dissolving one or more active substances, electrolytes or osmotically active substances in water complying with the requirements for *Water for injections* (0169) or they consist of such water alone. In the latter case, the preparation may be labelled as water for irrigation. Irrigation solutions are usually adjusted to be isotonic with blood.

Examined in suitable conditions of visibility, preparations for irrigation are clear and practically free from particles.

Preparations for irrigation are supplied in single-dose containers. The containers and closures comply with the requirements for containers for preparations for parenteral use (3.2.1 and 3.2.2) but the administration port of the container is incompatible with intravenous administration equipment and does not allow the preparation for irrigation to be administered with such equipment.

PRODUCTION

Preparations for irrigation are prepared using materials and methods designed to ensure sterility and to avoid the introduction of contaminants and the growth of micro-organisms; recommendations on this aspect are provided in the text on *Methods of preparation of sterile products* (5.1.1).

TESTS

Deliverable mass or volume (2.9.28). Preparations for irrigation supplied in single-dose containers comply with the test.

Sterility (2.6.1). Preparations for irrigation comply with the test for sterility.

Bacterial endotoxins (2.6.14): less than 0.5 IU/ml.

Pyrogens (2.6.8). Preparations for which a validated test for bacterial endotoxins cannot be carried out comply with the test for pyrogens. Inject per kilogram of the rabbits mass, 10 ml of the preparation, unless otherwise justified and authorised.

LABELLING

The label states:

- that the preparation is not to be used for injection,
- that the preparation is to be used for one occasion only and that any unused portion of preparation is to be discarded.

Additional requirements for preparations presented in pressurised containers may be found, where appropriate, in other general monographs, for example Preparations for inhalation (0671), Liquid preparations for cutaneous application (0927), Powders for cutaneous application (1166), Nasal preparations (0676) and Ear preparations (0652).

DEFINITION

Pressurised pharmaceutical preparations are presented in special containers under pressure of a gas and contain one or more active substances. The preparations are released from the container, upon actuation of an appropriate valve, in the form of an aerosol (dispersion of solid or liquid particles in a gas, the size of the particles being adapted to the intended use) or of a liquid or semisolid jet such as a foam. The pressure for the release is generated by suitable propellants.

The preparations consist of a solution, an emulsion or a suspension and are intended for local application to the skin or to mucous membranes of various body orifices, or for inhalation. Suitable excipients may also be used, for example solvents, solubilisers, emulsifying agents, suspending agents and lubricants for the valve to prevent clogging.

Propellants. The propellants are either gases liquefied under pressure or compressed gases or low-boiling liquids. Liquefied gases are, for example, fluorinated hydrocarbons and low-molecular-mass hydrocarbons (such as propane and butane). Compressed gases are, for example, carbon dioxide, nitrogen and nitrous oxide.

Mixtures of these propellants may be used to obtain optimal solution properties and desirable pressure, delivery and spray characteristics.

Containers. The containers are tight and resistant to the internal pressure and may be made of metal, glass, plastic or combinations of these materials. They are compatible with their contents. Glass containers are protected with a plastic coating.

Spraying device. The valve keeps the container tightly closed when not in use and regulates the delivery of the contents during use. The spray characteristics are influenced by the type of spraying device, in particular by the dimensions, number and location of orifices. Some valves provide a continuous release, others ("metering dose valves") deliver a defined quantity of product upon each valve actuation.

The various valve materials in contact with the contents are compatible with them.

Requirements for pressurised pharmaceutical preparations. Pressurised preparations are provided with a delivery device appropriate for the intended application.

Special requirements may be necessary for the selection of propellants, for particle size and the single-dose delivered by the metering valves.

LABELLING

The label states:

- the method of use,
- any precautions to be taken,

- for a container with a metering dose valve, the amount of active substance in a unit-spray.

01/2005:1145

RECTAL PREPARATIONS

Rectalia

DEFINITION

Rectal preparations are intended for rectal use in order to obtain a systemic or local effect, or they may be intended for diagnostic purposes.

Where applicable, containers for rectal preparations comply with the requirements for *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

Several categories of rectal preparations may be distinguished:

- suppositories,
- rectal capsules,
- rectal solutions, emulsions and suspensions,
- powders and tablets for rectal solutions and suspensions,
- semi-solid rectal preparations,
- rectal foams,
- rectal tampons.

PRODUCTION

During the development of a rectal preparation, the formulation for which contains an antimicrobial preservative, the effectiveness of the chosen preservative shall be demonstrated to the satisfaction of the competent authority. A suitable test method together with criteria for judging the preservative properties of the formulation are provided in the text on *Efficacy of antimicrobial preservation* (5.1.3).

In the manufacture, packaging, storage and distribution of rectal preparations, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

In the manufacture of semi-solid and liquid rectal preparations containing dispersed particles measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, solid single-dose preparations with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test A (tablets) or test B (suppositories, rectal capsules) for uniformity of content of single-dose preparations. If the preparation contains more than one active substance, this requirement applies only to those substances that correspond to the above conditions.

Uniformity of mass (2.9.5). Solid, single-dose preparations comply with the test for uniformity of mass. If the test for uniformity of content is prescribed for all active substances, the test for uniformity of mass is not required.

Deliverable mass or volume (2.9.28). Liquid and semi-solid rectal preparations supplied in single-dose containers comply with the test.

Dissolution. A suitable test may be required to demonstrate the appropriate release of the active substance(s) from solid, single-dose preparations, for example the dissolution test for suppositories and soft capsules (2.9.3).

Where a dissolution test is prescribed, a disintegration test may not be required.

LABELLING

The label states the name of any added antimicrobial preservative.

Suppositories

DEFINITION

Suppositories are solid, single-dose preparations. The shape, volume and consistency of suppositories are suitable for rectal administration.

They contain one or more active substances dispersed or dissolved in a suitable basis which may be soluble or dispersible in water or may melt at body temperature. Excipients such as diluents, adsorbents, surface-active agents, lubricants, antimicrobial preservatives and colouring matter, authorised by the competent authority, may be added if necessary.

PRODUCTION

Suppositories are prepared by compression or moulding. If necessary, the active substance(s) are previously ground and sieved through a suitable sieve. When prepared by moulding, the medicated mass, sufficiently liquified by heating, is poured into suitable moulds. The suppository solidifies on cooling. Various excipients are available for this process, such as hard fat, macrogols, cocoa butter, and various gelatinous mixtures consisting of, for example, gelatin, water and glycerol. Where applicable, the determination of the softening time of lipophilic suppositories (2.9.22) and/or the determination of the resistance to rupture of suppositories (2.9.24) are carried out.

A suitable test is carried out to demonstrate the appropriate release of the active substance(s) from suppositories intended for modified release or for prolonged local action.

In the manufacture of suppositories containing dispersed active substances, measures are taken to ensure a suitable and controlled particle size.

TESTS

Disintegration. Unless intended for modified release or for prolonged local action, they comply with the test for disintegration of suppositories and pessaries (2.9.2). For suppositories with a fatty base, examine after 30 min and for suppositories with a water-soluble base after 60 min, unless otherwise justified and authorised.

Rectal capsules

DEFINITION

Rectal capsules (shell suppositories) are solid, single-dose preparations generally similar to soft capsules as defined in the monograph on *Capsules* (0016) except that they may have lubricating coatings. They are of elongated shape, are smooth and have a uniform external appearance.

PRODUCTION

A suitable test is carried out to demonstrate the appropriate release of the active substance(s) from rectal capsules intended for modified release or for prolonged local action.

TESTS

Disintegration. Unless intended for modified release or for prolonged local action, they comply with the test for disintegration of suppositories and pessaries (2.9.2). Examine the state of the capsules after 30 min, unless otherwise justified and authorised.

Rectal solutions, emulsions and suspensions

DEFINITION

Rectal solutions, emulsions and suspensions are liquid preparations intended for rectal use in order to obtain a systemic or local effect, or they may be intended for diagnostic purposes.

Rectal solutions, emulsions and suspensions are supplied in single-dose containers and they contain one or more active substances dissolved or dispersed in water, glycerol or macrogols or other suitable solvents. Emulsions may show evidence of phase separation but are readily redispersed on shaking. Suspensions may show a sediment which is readily dispersible on shaking to give a suspension which remains sufficiently stable to enable the correct dose to be delivered.

Rectal solutions, emulsions and suspensions may contain excipients, for example to adjust the viscosity of the preparation, to adjust or stabilise the pH, to increase the solubility of the active substance(s) or to stabilise the preparation. These substances do not adversely affect the intended medical action or, at the concentrations used, cause undue local irritation.

Rectal solutions, emulsions and suspensions are supplied in containers containing a volume in the range of 2.5 ml to 2000 ml. The container is adapted to deliver the preparation to the rectum or it is accompanied by a suitable applicator.

Powders and tablets for rectal solutions and suspensions

DEFINITION

Powders and tablets intended for the preparation of rectal solutions or suspensions are single-dose preparations which are dissolved or dispersed in water at the time of administration. They may contain excipients to facilitate dissolution or dispersion or to prevent aggregation of the particles.

After dissolution or suspension, they comply with the requirements for rectal solutions or rectal suspensions, as appropriate.

TESTS

Disintegration. Tablets for rectal solutions or suspensions disintegrate within 3 min when tested according to the test for disintegration of tablets and capsules (2.9.1) but using *water R* at 15 °C to 25 °C.

LABELLING

The label states:

- the method of preparation of the rectal solution or suspension,
- the conditions and duration of storage of the solution or suspension after constitution.

Semi-solid rectal preparations

DEFINITION

Semi-solid rectal preparations are ointments, creams or gels.

They are often supplied as single-dose preparations in containers provided with a suitable applicator.

Semi-solid rectal preparations comply with the requirements of the monograph on *Semi-solid preparations for cutaneous application* (0132).

Rectal foams

DEFINITION

Rectal foams comply with the requirements of the monograph on *Medicated foams* (1105).

Rectal tampons

DEFINITION

Rectal tampons are solid, single-dose preparations intended to be inserted into the lower part of the rectum for a limited time.

They comply with the requirements of the monograph on *Medicated tampons* (1155).

01/2005:0132

SEMI-SOLID PREPARATIONS FOR CUTANEOUS APPLICATION

Praeparationes molles ad usum dermicum

The requirements of this monograph apply to all semi-solid preparations for cutaneous application. Where appropriate, additional requirements specific to semi-solid preparations intended to be applied to particular surfaces or mucous membranes may be found in other general monographs, for example Ear preparations (0652), Nasal preparations (0676), Rectal preparations (1145), Eye preparations (1163) and Vaginal preparations (1164).

DEFINITION

Semi-solid preparations for cutaneous application are intended for local or transdermal delivery of active substances, or for their emollient or protective action. They are of homogeneous appearance.

Semi-solid preparations for cutaneous application consist of a simple or compound basis in which, usually, one or more active substances are dissolved or dispersed. According to its composition, the basis may influence the activity of the preparation.

The basis may consist of natural or synthetic substances and may be single phase or multiphase. According to the nature of the basis, the preparation may have hydrophilic or hydrophobic properties; it may contain suitable excipients such as antimicrobial preservatives, antioxidants, stabilisers, emulsifiers, thickeners and penetration enhancers.

Semi-solid preparations for cutaneous application intended for use on severely injured skin are sterile.

Where applicable, containers for semi-solid preparations for cutaneous application comply with the requirements for *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

Several categories of semi-solid preparations for cutaneous application may be distinguished:

- ointments,
- creams,
- gels,
- pastes,

- poultices,
- medicated plasters.

According to their structure, ointments, creams and gels generally show viscoelastic behaviour and are non-newtonian in character e.g. plastic, pseudoplastic or thixotropic type flow at high shear rates. Pastes frequently exhibit dilatancy.

PRODUCTION

During the development of semi-solid preparations for cutaneous application whose formulation contains an antimicrobial preservative, the necessity for and the effectiveness of the chosen preservative shall be demonstrated to the satisfaction of the competent authority. A suitable test method together with criteria for judging the preservative properties of the formulation are provided in *Efficacy of antimicrobial preservation (5.1.3)*. In the manufacture, packaging, storage and distribution of semi-solid preparations for cutaneous application, suitable steps are taken to ensure their microbiological quality; recommendations on this are provided in *Microbiological Quality of Pharmaceutical Preparations (5.1.4)*. Sterile semi-solid preparations for cutaneous application are prepared using materials and methods designed to ensure sterility and to avoid the introduction of contaminants and the growth of micro-organisms; recommendations on this are provided in *Methods of Preparation of Sterile Products (5.1.1)*.

In the manufacture of semi-solid preparations for cutaneous application, suitable measures are taken to ensure that the defined rheological properties are fulfilled. Where appropriate, the following non-mandatory tests may be carried out: measurement of consistency by penetrometry (2.9.9), viscosity (apparent viscosity) (2.2.10) and a suitable test to demonstrate the appropriate release of the active substance(s).

In the manufacture of semi-solid preparations for cutaneous application containing (an) active substance(s) which is/are not dissolved in the basis (e.g. emulsions or suspensions), measures are taken to ensure appropriate homogeneity of the preparation to be delivered.

In the manufacture of semi-solid preparations for cutaneous application containing dispersed particles, measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

TESTS

Deliverable mass or volume (2.9.28). Semi-solid preparations for cutaneous application supplied in single-dose containers comply with the test.

Sterility (2.6.1). Where the label indicates that the preparation is sterile, it complies with the test for sterility.

STORAGE

If the preparation contains water or other volatile ingredients, store in an airtight container. If the preparation is sterile, store in a sterile, airtight, tamper-proof container.

LABELLING

The label states:

- the name of any added antimicrobial preservative,
- where applicable, that the preparation is sterile.

Ointments

DEFINITION

An ointment consists of a single-phase basis in which solids or liquids may be dispersed.

Hydrophobic Ointments

Hydrophobic ointments can absorb only small amounts of water. Typical bases used for their formulation are hard, liquid and light liquid paraffins, vegetable oils, animal fats, synthetic glycerides, waxes and liquid polyalkylsiloxanes.

Water-emulsifying Ointments

Water-emulsifying ointments can absorb larger amounts of water and thereby produce water-in-oil or oil-in-water emulsions depending on the nature of the emulsifiers: water-in-oil emulsifying agents such as wool alcohols, sorbitan esters, monoglycerides and fatty alcohols, or oil-in-water emulsifying agents such as sulphated fatty alcohols, polysorbates, macrogol cetostearyl ether or esters of fatty acids with macrogols may be used for this purpose. Their bases are those of the hydrophobic ointments.

Hydrophilic Ointments

Hydrophilic ointments are preparations having bases that are miscible with water. The bases usually consist of mixtures of liquid and solid macrogols (polyethylene glycols). They may contain appropriate amounts of water.

Creams

DEFINITION

Creams are multiphase preparations consisting of a lipophilic phase and an aqueous phase.

Lipophilic Creams

Lipophilic creams have as the continuous phase the lipophilic phase. They contain water-in-oil emulsifying agents such as wool alcohols, sorbitan esters and monoglycerides.

Hydrophilic Creams

Hydrophilic creams have as the continuous phase the aqueous phase. They contain oil-in-water emulsifying agents such as sodium or trolamine soaps, sulphated fatty alcohols, polysorbates and polyoxyl fatty acid and fatty alcohol esters combined, if necessary, with water-in-oil emulsifying agents.

Gels

DEFINITION

Gels consist of liquids gelled by means of suitable gelling agents.

Lipophilic Gels

Lipophilic gels (oleogels) are preparations whose bases usually consist of liquid paraffin with polyethylene or fatty oils gelled with colloidal silica or aluminium or zinc soaps.

Hydrophilic Gels

Hydrophilic gels (hydrogels) are preparations whose bases usually consist of water, glycerol or propylene glycol gelled with suitable gelling agents such as starch, cellulose derivatives, carbomers and magnesium-aluminium silicates.

Pastes

DEFINITION

Pastes are semi-solid preparations for cutaneous application containing large proportions of solids finely dispersed in the basis.

Poultices

DEFINITION

Poultices consist of a hydrophilic heat-retentive basis in which solid or liquid active substances are dispersed. They are usually spread thickly on a suitable dressing and heated before application to the skin.

Medicated plasters

DEFINITION

Medicated plasters are flexible preparations containing one or more active substances. They are intended to be applied to the skin. They are designed to maintain the active substance(s) in close contact with the skin such that these may be absorbed slowly, or act as protective or keratolytic agents.

Medicated plasters consist of an adhesive basis, which may be coloured, containing one or more active substances, spread as a uniform layer on an appropriate support made of natural or synthetic material. It is not irritant or sensitising to the skin. The adhesive layer is covered by a suitable protective liner, which is removed before applying the plaster to the skin. When removed, the protective liner does not detach the preparation from the outer, supporting layer.

Medicated plasters are presented in a range of sizes directly adapted to their intended use or as larger sheets to be cut before use. Medicated plasters adhere firmly to the skin when gentle pressure is applied and can be peeled off without causing appreciable injury to the skin or detachment of the preparation from the outer, supporting layer.

TESTS

Dissolution. A suitable test may be required to demonstrate the appropriate release of the active substance(s), for example one of the tests described in *Dissolution test for transdermal patches* (2.9.4).

01/2005:1154

STICKS

Styli

Additional requirements for sticks may be found, where appropriate, in other general monographs, for example Nasal preparations (0676).

DEFINITION

Sticks are solid preparations intended for local application. They are rod-shaped or conical preparations consisting of one or more active substances alone or which are dissolved or dispersed in a suitable basis which may dissolve or melt at body temperature.

Urethral sticks and sticks for insertion into wounds are sterile.

PRODUCTION

In the manufacture, packaging, storage and distribution of sticks, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

Urethral sticks and other sterile sticks are prepared using materials and methods designed to ensure sterility and to avoid the introduction of contaminants and the growth of micro-organisms; recommendations on this aspect are provided in the text on *Methods of preparation of sterile products* (5.1.1).

In the manufacture of sticks means are taken to ensure that the preparation complies with a test for mass uniformity or, where appropriate, a test for uniformity of content.

TESTS

Sterility (2.6.1). Urethral sticks and sticks for insertion into wounds comply with the test for sterility.

LABELLING

The label states:

- the quantity of active substance(s) per stick,
- for urethral sticks and sticks to be inserted into wounds that they are sterile.

01/2005:0478

TABLETS

Compressi

The requirements of this monograph do not necessarily apply to preparations that are presented as tablets intended for use other than by oral administration. Requirements for such preparations may be found, where appropriate, in other general monographs; for example Rectal preparations (1145), Vaginal preparations (1164) and Oromucosal preparations (1807). This monograph does not apply to lozenges, oral lyophilisates, oral pastes and oral gums. Where justified and authorised, the requirements of this monograph do not apply to tablets for veterinary use.

DEFINITION

Tablets are solid preparations each containing a single dose of one or more active substances and usually obtained by compressing uniform volumes of particles. Tablets are intended for oral administration. Some are swallowed whole, some after being chewed, some are dissolved or dispersed in water before being administered and some are retained in the mouth where the active substance is liberated.

The particles consist of one or more active substances with or without excipients such as diluents, binders, disintegrating agents, glidants, lubricants, substances capable of modifying the behaviour of the preparation in the digestive tract, colouring matter authorised by the competent authority and flavouring substances.

Tablets are usually right, circular solid cylinders, the end surfaces of which are flat or convex and the edges of which may be bevelled. They may have lines or break-marks and may bear a symbol or other markings. Tablets may be coated.

Where applicable, containers for tablets comply with the requirements for *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

Several categories of tablets for oral use may be distinguished:

- uncoated tablets,
- coated tablets,
- effervescent tablets,
- soluble tablets,
- dispersible tablets,
- orodispersible tablets,
- gastro-resistant tablets,
- modified-release tablets.

PRODUCTION

Tablets are usually prepared by compressing uniform volumes of particles or particle aggregates produced by granulation methods. In the manufacture of tablets, means are taken to ensure that they possess a suitable mechanical strength to avoid crumbling or breaking on handling or subsequent processing. This may be demonstrated by examining the *Friability of uncoated tablets* (2.9.7) and the *Resistance to crushing of tablets* (2.9.8). Chewable tablets are prepared to ensure that they are easily crushed by chewing.

For tablets for which subdivision is authorised, it is demonstrated to the satisfaction of the competent authority that the subdivided parts comply either with test A for *Uniformity of content of single-dose preparations* (2.9.6) or with the test for *Uniformity of mass of single-dose preparations* (2.9.5), as appropriate.

In the manufacture, packaging, storage and distribution of tablets, suitable means are taken to ensure their microbiological quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, tablets with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test A for uniformity of content of single-dose preparations. If the preparation has more than one active substance, the requirement applies only to those substances which correspond to the above conditions.

Unless otherwise justified and authorised, coated tablets other than film-coated tablets comply with test A for uniformity of content of single-dose preparations irrespective of their content of active substance(s).

Uniformity of mass (2.9.5). Uncoated tablets and, unless otherwise justified and authorised, film-coated tablets comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed or justified and authorised for all the active substances, the test for uniformity of mass is not required.

Dissolution. A suitable test may be carried out to demonstrate the appropriate release of the active substance(s), for example one of the tests described in *Dissolution test for solid dosage forms* (2.9.3).

Where a dissolution test is prescribed, a disintegration test may not be required.

Uncoated tablets

DEFINITION

Uncoated tablets include single-layer tablets resulting from a single compression of particles and multi-layer tablets consisting of concentric or parallel layers obtained by successive compression of particles of different composition. The excipients used are not specifically intended to modify the release of the active substance in the digestive fluids.

Uncoated tablets conform to the general definition of tablets. A broken section, when examined under a lens, shows either a relatively uniform texture (single-layer tablets) or a stratified texture (multi-layer tablets) but no signs of coating.

TESTS

Disintegration. Uncoated tablets comply with the test for disintegration of tablets and capsules (2.9.1). Use *water R* as the liquid. Add a disc to each tube. Operate the apparatus for 15 min, unless otherwise justified and authorised, and examine the state of the tablets. If the tablets fail to comply because of adherence to the discs, repeat the test on a further 6 tablets omitting the discs. The tablets comply with the test if all 6 have disintegrated.

Chewable tablets are not required to comply with the test.

Coated tablets

DEFINITION

Coated tablets are tablets covered with one or more layers of mixtures of various substances such as natural or synthetic resins, gums, gelatin, inactive and insoluble fillers, sugars, plasticisers, polyols, waxes, colouring matter authorised by the competent authority and sometimes flavouring substances and active substances. The substances used as coatings are usually applied as a solution or suspension in conditions in which evaporation of the vehicle occurs. When the coating is a very thin polymeric coating, the tablets are known as film-coated tablets.

Coated tablets have a smooth surface which is often coloured and may be polished; a broken section, when examined under a lens, shows a core surrounded by one or more continuous layers with a different texture.

PRODUCTION

Where justified, uniformity of mass or uniformity of content of coated tablets other than film-coated tablets may be ensured by control of the cores.

TESTS

Disintegration. Coated tablets other than film-coated tablets comply with the test for disintegration of tablets and capsules (2.9.1). Use *water R* as the liquid. Add a disc to each tube. Operate the apparatus for 60 min, unless otherwise justified and authorised, and examine the state of the tablets. If any of the tablets has not disintegrated, repeat the test on a further 6 tablets, replacing *water R* with *0.1 M hydrochloric acid*. The tablets comply with the test if all 6 have disintegrated in the acid medium.

Film-coated tablets comply with the disintegration test prescribed above except that the apparatus is operated for 30 min, unless otherwise justified and authorised.

If coated tablets or film-coated tablets fail to comply because of adherence to the discs, repeat the test on a further 6 tablets omitting the discs. The tablets comply with the test if all 6 have disintegrated.

Chewable coated tablets are not required to comply with the test.

Effervescent tablets

DEFINITION

Effervescent tablets are uncoated tablets generally containing acid substances and carbonates or hydrogen carbonates which react rapidly in the presence of water to release carbon dioxide. They are intended to be dissolved or dispersed in water before administration.

TESTS

Disintegration. Place 1 tablet in a beaker containing 200 ml of *water R* at 15-25 °C; numerous bubbles of gas are evolved. When the evolution of gas around the tablet or its fragments ceases the tablet has disintegrated, being either dissolved or dispersed in the water so that no agglomerates of particles remain. Repeat the operation on 5 other tablets. The tablets comply with the test if each of the 6 tablets used disintegrates in the manner prescribed within 5 min, unless otherwise justified and authorised.

Soluble tablets

DEFINITION

Soluble tablets are uncoated or film-coated tablets. They are intended to be dissolved in water before administration. The solution produced may be slightly opalescent due to the added excipients used in the manufacture of the tablets.

TESTS

Disintegration. Soluble tablets disintegrate within 3 min when examined by the test for disintegration of tablets and capsules (2.9.1), but using *water R* at 15-25 °C.

Dispersible tablets

DEFINITION

Dispersible tablets are uncoated or film-coated tablets intended to be dispersed in water before administration giving a homogeneous dispersion.

TESTS

Disintegration. Dispersible tablets disintegrate within 3 min when examined by the test for disintegration of tablets and capsules (2.9.1), but using *water R* at 15-25 °C.

Fineness of dispersion. Place 2 tablets in 100 ml of *water R* and stir until completely dispersed. A smooth dispersion is produced, which passes through a sieve screen with a nominal mesh aperture of 710 µm.

Orodispersible tablets

DEFINITION

Orodispersible tablets are uncoated tablets intended to be placed in the mouth where they disperse rapidly before being swallowed.

TESTS

Disintegration. Orodispersible tablets disintegrate within 3 min when examined by the test for disintegration of tablets and capsules (2.9.1).

Modified-release tablets

DEFINITION

Modified-release tablets are coated or uncoated tablets which contain special excipients or which are prepared by special procedures, or both, designed to modify the rate, the place or the time at which the active substance(s) are released.

Modified-release tablets include prolonged-release tablets, delayed-release tablets and pulsatile-release tablets.

PRODUCTION

A suitable test is carried out to demonstrate the appropriate release of the active substance(s).

Gastro-resistant tablets

DEFINITION

Gastro-resistant tablets are delayed-release tablets that are intended to resist the gastric fluid and to release their active substance(s) in the intestinal fluid. Usually they are prepared from granules or particles already covered with a gastro-resistant coating or in certain cases by covering tablets with a gastro-resistant coating (enteric-coated tablets).

Tablets covered with a gastro-resistant coating conform to the definition of coated tablets.

PRODUCTION

For tablets prepared from granules or particles already covered with a gastro-resistant coating, a suitable test is carried out to demonstrate the appropriate release of the active substance(s).

TESTS

Disintegration. For tablets covered with a gastro-resistant coating carry out the test for disintegration (2.9.1) with the following modifications. Use *0.1 M hydrochloric acid* as the liquid. Operate the apparatus for 2 h, or other such time as may be justified and authorised, without the discs and examine the state of the tablets. The time of resistance to the acid medium varies according to the formulation of the tablets to be examined. It is typically 2 h to 3 h but even with authorised deviations is not less than 1 h. No tablet shows signs of either disintegration (apart from fragments of coating) or cracks that would allow the escape of the contents. Replace the acid by *phosphate buffer solution pH 6.8 R* and add a disc to each tube. Operate the apparatus for 60 min and examine the state of the tablets. If the tablets fail to comply because of adherence to the discs, repeat the test on a further 6 tablets omitting the discs. The tablets comply with the test if all 6 have disintegrated.

Dissolution. For tablets prepared from granules or particles already covered with a gastro-resistant coating, a suitable test is carried out to demonstrate the appropriate release of the active substance(s), for example the test described in *Dissolution test for solid dosage forms* (2.9.3).

Tablets for use in the mouth

DEFINITION

Tablets for use in the mouth are usually uncoated tablets. They are formulated to effect a slow release and local action of the active substance(s) or the release and absorption of the active substance or substances at a defined part of the mouth. They comply with the requirements of the monograph on *Oromucosal preparations* (1807).

01/2005:1155

TAMPONS, MEDICATED

Tamponae medicatae

Additional requirements for medicated tampons may be found, where appropriate, in other general monographs, for example Rectal preparations (1145), Vaginal preparations (1164) and Ear preparations (0652).

DEFINITION

Medicated tampons are solid, single-dose preparations intended to be inserted into the body cavities for a limited period of time. They consist of a suitable material such as cellulose, collagen or silicone impregnated with one or more active substances.

PRODUCTION

In the manufacture, packaging, storage and distribution of medicated tampons, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

LABELLING

The label states the quantity of active substance(s) per tampon.

01/2005:1164

VAGINAL PREPARATIONS

Vaginalia

DEFINITION

Vaginal preparations are liquid, semi-solid or solid preparations intended for administration to the vagina usually in order to obtain a local effect. They contain one or more active substances in a suitable basis.

Where appropriate, containers for vaginal preparations comply with the requirements for *Materials used for the manufacture of containers* (3.1 and subsections) and *Containers* (3.2 and subsections).

Several categories of vaginal preparations may be distinguished:

- pessaries,
- vaginal tablets,
- vaginal capsules,
- vaginal solutions, emulsions and suspensions,
- tablets for vaginal solutions and suspensions,
- semi-solid vaginal preparations,
- vaginal foams,
- medicated vaginal tampons.

PRODUCTION

In the manufacturing, packaging, storage and distribution of vaginal preparations, suitable means are taken to ensure their microbial quality; recommendations on this aspect are provided in the text on *Microbiological quality of pharmaceutical preparations* (5.1.4).

TESTS

Uniformity of content (2.9.6). Unless otherwise prescribed or justified and authorised, solid single-dose preparations with a content of active substance less than 2 mg or less than 2 per cent of the total mass comply with test A (vaginal tablets) or test B (pessaries, vaginal capsules) for uniformity of content of single-dose preparations. If the preparation has more than one active substance, the requirement applies only to those substances which correspond to the above conditions.

Uniformity of mass (2.9.5). Solid single-dose vaginal preparations comply with the test for uniformity of mass of single-dose preparations. If the test for uniformity of content is prescribed for all the active substances, the test for uniformity of mass is not required.

Deliverable mass or volume (2.9.28). Liquid and semi-solid vaginal preparations supplied in single-dose containers comply with the test.

Dissolution. A suitable test may be carried out to demonstrate the appropriate release of the active substance(s) from solid single-dose preparations, for example one of the tests described in *Dissolution test for solid dosage forms* (2.9.3).

When a dissolution test is prescribed, a disintegration test may not be required.

Pessaries

DEFINITION

Pessaries are solid, single-dose preparations. They have various shapes, usually ovoid, with a volume and consistency suitable for insertion into the vagina. They contain one or

more active substances dispersed or dissolved in a suitable basis that may be soluble or dispersible in water or may melt at body temperature. Excipients such as diluents, adsorbents, surface-active agents, lubricants, antimicrobial preservatives and colouring matter authorised by the competent authority may be added, if necessary.

PRODUCTION

Pessaries are usually prepared by moulding. Where appropriate in the manufacture of pessaries, measures are taken to ensure a suitable and controlled particle size of the active substance(s). If necessary, the active substance(s) are previously ground and sieved through a suitable sieve.

When prepared by moulding, the medicated mass, sufficiently liquified by heating, is poured into suitable moulds. The pessary solidifies on cooling. Various excipients are available for this process, such as hard fat, macrogols, cocoa butter, and various gelatinous mixtures consisting, for example, of gelatin, water and glycerol.

A suitable test is carried out to demonstrate the appropriate release of the active substance(s) from pessaries intended for prolonged local action.

Where appropriate, the determination of the resistance to rupture of pessaries (2.9.24) is carried out.

TESTS

Disintegration. Unless intended for prolonged local action, they comply with the test for disintegration of suppositories and pessaries (2.9.2). Examine the state of the pessaries after 60 min, unless otherwise justified and authorised.

Vaginal tablets

DEFINITION

Vaginal tablets are solid, single-dose preparations. They generally conform to the definitions of uncoated or film-coated tablets given in the monograph on *Tablets* (0478).

PRODUCTION

A suitable test is carried out to demonstrate the appropriate release of the active substance(s) from vaginal tablets intended for prolonged local action.

TESTS

Disintegration. Unless intended for prolonged local action, they comply with the test for disintegration of suppositories and pessaries (special method for vaginal tablets, 2.9.2). Examine the state of the tablets after 30 min, unless otherwise justified and authorised.

Vaginal capsules

DEFINITION

Vaginal capsules (shell pessaries) are solid, single-dose preparations. They are generally similar to soft capsules, differing only in their shape and size. Vaginal capsules have various shapes, usually ovoid. They are smooth and have a uniform external appearance.

PRODUCTION

A suitable test is carried out to demonstrate the appropriate release of the active substance(s) from vaginal capsules intended for prolonged local action.

TESTS

Disintegration. Unless intended for prolonged local action, they comply with the test for disintegration of suppositories and pessaries (2.9.2). Examine the state of the capsules after 30 min, unless otherwise justified and authorised.

Vaginal solutions, emulsions and suspensions

DEFINITION

Vaginal solutions, emulsions and suspensions are liquid preparations intended for a local effect, for irrigation or for diagnostic purposes. They may contain excipients, for example to adjust the viscosity of the preparation, to adjust or stabilise the pH, to increase the solubility of the active substance(s) or to stabilise the preparation. The excipients do not adversely affect the intended medical action or, at the concentrations used, cause undue local irritation.

Vaginal emulsions may show evidence of phase separation but are readily redispersed on shaking. Vaginal suspensions may show a sediment that is readily dispersed on shaking to give a suspension which remains sufficiently stable to enable a homogeneous preparation to be delivered.

They are supplied in single-dose containers. The container is adapted to deliver the preparation to the vagina or it is accompanied by a suitable applicator.

PRODUCTION

In the manufacture of vaginal suspensions measures are taken to ensure a suitable and controlled particle size with regard to the intended use.

Tablets for vaginal solutions and suspensions

DEFINITION

Tablets intended for the preparation of vaginal solutions and suspensions are single-dose preparations which are dissolved or dispersed in water at the time of administration. They may contain excipients to facilitate dissolution or dispersion or to prevent caking.

Apart from the test for disintegration, tablets for vaginal solutions or suspensions conform with the definition for *Tablets* (0478).

After dissolution or dispersion, they comply with the requirements for vaginal solutions or vaginal suspensions, as appropriate.

TESTS

Disintegration. Tablets for vaginal solutions or suspensions disintegrate within 3 min when tested according to the test for disintegration of tablets and capsules (2.9.1), but using *water R* at 15 °C to 25 °C.

LABELLING

The label states:

- the method of preparation of the vaginal solution or suspension,
- the conditions and duration of storage of the solution or suspension after constitution.

Semi-solid vaginal preparations

DEFINITION

Semi-solid vaginal preparations are ointments, creams or gels.

They are often supplied in single-dose containers. The container is provided with a suitable applicator.

Semi-solid vaginal preparations comply with the requirements of the monograph on *Semi-solid preparations for cutaneous application* (0132).

Vaginal foams

DEFINITION

Vaginal foams comply with the requirements of the monograph on *Medicated foams* (1105).

Medicated vaginal tampons

DEFINITION

Medicated vaginal tampons are solid, single-dose preparations intended to be inserted in the vagina for a limited time.

They comply with the requirements of the monograph on *Medicated tampons* (1155).

01/2005:1808

VETERINARY LIQUID PREPARATIONS FOR CUTANEOUS APPLICATION

Praeparationes liquidae veterinariae ad usum dermicum

Unless otherwise justified and authorised, veterinary liquid preparations for cutaneous application comply with the requirements of the monograph on Liquid preparations for cutaneous application (0927). In addition to these requirements, the following statements apply to veterinary liquid preparations for cutaneous application.

DEFINITION

Veterinary liquid preparations for cutaneous application are liquid preparations intended to be applied to the skin to obtain a local and/or systemic effect. They are solutions, suspensions or emulsions which may contain one or more active substances in a suitable vehicle. They may be presented as concentrates in the form of wettable powders, pastes, solutions or suspensions, which are used to prepare diluted suspensions or emulsions of active substances. They may contain suitable antimicrobial preservatives, antioxidants and other excipients such as stabilisers, emulsifiers and thickeners.

Several categories of veterinary liquid preparations for cutaneous application may be distinguished:

- cutaneous foams (see *Liquid preparations for cutaneous application* (0927)),
- dip concentrates,
- pour-on preparations,
- shampoos (see *Liquid preparations for cutaneous application* (0927)),
- spot-on preparations,
- sprays,
- teat dips,
- teat sprays,
- udder-washes.

Dip concentrates

DEFINITION

Dip concentrates are preparations containing one or more active substances, usually in the form of wettable powders, pastes, solutions or suspensions, which are used to prepare diluted solutions, suspensions or emulsions of active substances. The diluted preparations are applied by complete immersion of the animal.

Pour-on preparations

DEFINITION

Pour-on preparations contain one or more active substances for the prevention and treatment of ectoparasitic and/or endoparasitic infestations of animals. They are applied in volumes which are usually greater than 5 ml by pouring along the animal's dorsal midline.

Spot-on preparations

DEFINITION

Spot-on preparations contain one or more active substances for the prevention and treatment of ectoparasitic and/or endoparasitic infestations of animals. They are applied in volumes which are usually less than 10 ml, to a small area on the head or back, as appropriate, of the animal.

Sprays

DEFINITION

Sprays contain one or more active substances that are intended to be applied externally for therapeutic or prophylactic purposes. They are delivered in the form of an aerosol by the actuation of an appropriate valve or by means of a suitable atomising device that is either an integral part of the container or is supplied separately.

Sprays may be presented in pressurised containers (see *Pressurised pharmaceutical preparations (0523)*). When so presented, sprays usually consist of one or more active substances in a suitable vehicle held under pressure with suitable propellants or suitable mixtures of propellants. When otherwise presented, sprays are supplied in well-closed containers.

PRODUCTION

During the development and manufacture of a spray, measures are taken to ensure that the assembled product conforms to a defined spray rate and spray pattern.

Teat dips

DEFINITION

Teat dips contain one or more disinfectant active substances, usually in the form of solutions into which the teats of an animal are dipped pre- and, where necessary, post-milking to reduce the population of pathogenic micro-organisms on the surfaces. Teat dips may be supplied/presented as ready-to-use preparations or they may be prepared by dilution of teat dip concentrates. Pre- and post-milking teat dips often differ in formulation. Teat dips usually contain emollients to promote skin hydration, to soften the skin and allow healing of lesions that would otherwise harbour bacteria.

Teat sprays

DEFINITION

Teat sprays contain one or more disinfectant active substances, usually in the form of solutions which are sprayed onto the teats of an animal pre- and, where necessary, post-milking to reduce the population of pathogenic micro-organisms on the surfaces. Teat sprays may be supplied/presented as ready-to-use preparations or they may be prepared by dilution of teat spray concentrates. Pre- and post-milking sprays often differ in formulation. Teat sprays usually contain emollients to promote skin hydration, to soften the skin and allow healing of lesions that would otherwise harbour bacteria.

Udder-washes

DEFINITION

Udder-washes contain one or more disinfectant active substances, usually in the form of solutions which are sprayed onto the udder and teats of an animal to remove mud and faecal contamination before the application of teat dips or sprays. Udder-washes are usually prepared by the dilution either of concentrated preparations or of ready-to-use teat dips or teat sprays.

01/2005:1929 **Virulent mycobacteria.** Examine the working seed lot as prescribed under Tests, using 10 guinea-pigs.

BCG FOR IMMUNOTHERAPY

BCG ad immunocurationem

DEFINITION

BCG for immunotherapy is a freeze-dried preparation of live bacteria derived from a culture of the bacillus of Calmette and Guérin (*Mycobacterium bovis* BCG) whose capacity for treatment has been established.

It complies with the monograph *Vaccines for human use* (0153).

PRODUCTION

GENERAL PROVISIONS

BCG for immunotherapy shall be produced by a staff consisting of healthy persons who do not work with other infectious agents; in particular they shall not work with virulent strains of *Mycobacterium tuberculosis*, nor shall they be exposed to a known risk of tuberculosis infection. Staff are examined periodically for tuberculosis. BCG for immunotherapy is susceptible to sunlight: the procedures for production shall be so designed that all products are protected from direct sunlight and from ultraviolet light at all stages of manufacture, testing and storage.

Production is based on a seed-lot system. The production method shall have been shown to yield consistently BCG products that can be used for treatment of superficial bladder cancer and are safe. The product is prepared from cultures which are separated from the master seed lot by as few subcultures as possible and in any case not more than 8 subcultures. During the course of these subcultures the preparation is not freeze-dried more than once.

If a bioluminescence test or other biochemical method is used instead of viable count, the method is validated against the viable count for each stage of the process at which it is used.

SEED LOTS

The strain used to establish the master seed lot is chosen for and maintained to preserve its characteristics, its capacity to treat and prevent superficial bladder cancer, and its relative absence of pathogenicity for man and laboratory animals. The strain used shall be identified by historical records that include information on its origin and subsequent manipulation.

Before establishment of a working seed lot a batch is prepared and reserved for use as the comparison product. When a new working seed lot is established, a suitable test for delayed hypersensitivity in guinea-pigs is carried out on a batch of product prepared from the new working seed lot; the product is shown to be not significantly different in activity from the comparison product. Antimicrobial agent sensitivity testing is also carried out.

Only a working seed lot that complies with the following requirements may be used for propagation.

Identification. The bacteria in the working seed lot are identified as *Mycobacterium bovis* BCG using microbiological techniques, which may be supplemented by molecular biology techniques (for example, nucleic acid amplification and restriction-fragment-length polymorphism).

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml for each medium. The working seed lot complies with the test for sterility, except for the presence of mycobacteria.

PROPAGATION AND HARVEST

The bacteria are grown in a suitable medium for not more than 21 days by surface or submerged culture. The culture medium does not contain substances known to cause toxic or allergic reactions in human beings or to cause the bacteria to become virulent for guinea-pigs. The culture is harvested and suspended in a sterile liquid medium that protects the viability of the culture as determined by a suitable method of viable count.

FINAL BULK

The final bulk is prepared from a single harvest or by pooling a number of single harvests. A stabiliser may be added; if the stabiliser interferes with the determination of bacterial concentration on the final bulk, the determination is carried out before addition of the stabiliser.

Only final bulk that complies with the following requirements may be used in the preparation of the final lot.

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml of final bulk for each medium. The final bulk complies with the test for sterility, except for the presence of mycobacteria.

Count of viable units. Determine the number of viable units per millilitre by viable count on solid medium using a method suitable for the product to be examined or by a suitable biochemical method. Carry out the test in parallel on a reference preparation of the same strain.

Bacterial concentration. Determine the total bacterial concentration by a suitable method, either directly by determining the mass of the micro-organisms, or indirectly by an opacity method that has been calibrated in relation to the mass of the micro-organisms; if the bacterial concentration is determined before addition of a stabiliser, the concentration in the final bulk is established by calculation. The total bacterial concentration is within the limits approved for the particular product.

The ratio of the count of viable units to the total bacterial concentration is not less than that approved for the particular product.

FINAL LOT

The final bulk is distributed into sterile containers and freeze-dried to a moisture content favourable to the stability of the product; the containers are closed either under vacuum or under an inert gas.

Except where the filled and closed containers are stored at a temperature of -20°C or lower, the expiry date is not later than 4 years from the date of harvest.

Only a final lot that complies with the following requirement for count of viable units and with each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the test for virulent mycobacteria has been carried out with satisfactory results on the final bulk, it may be omitted on the final lot.

Count of viable units. Determine the number of viable units per millilitre of the reconstituted product by viable count on solid medium using a method suitable for the product to be examined, or by a suitable biochemical method. The ratio of the count of viable units after freeze-drying to that before is not less than that approved for the particular product.

IDENTIFICATION

BCG for immunotherapy is identified by microscopic examination of the bacilli in stained smears demonstrating their acid-fast property and by the characteristic appearance

of colonies grown on solid medium. Alternatively, molecular biology techniques (for example, nucleic acid amplification) may be used.

TESTS

Virulent mycobacteria. Inject subcutaneously or intramuscularly into each of 6 guinea-pigs, each weighing 250-400 g and having received no treatment likely to interfere with the test, a quantity of the product to be examined equivalent to at least 1/25 of 1 human dose. Observe the animals for at least 42 days. At the end of this period, kill the guinea-pigs and examine by autopsy for signs of infection with tuberculosis, ignoring any minor reactions at the site of injection. Animals that die during the observation period are also examined for signs of tuberculosis. The product complies with the test if none of the guinea-pigs shows signs of tuberculosis and if not more than 1 animal dies during the observation period. If 2 animals die during this period and autopsy does not reveal signs of tuberculosis, repeat the test on 6 other guinea-pigs. The product complies with the test if not more than 1 animal dies during the 42 days following the injection and autopsy does not reveal any sign of tuberculosis.

Bacterial and fungal contamination. The reconstituted product complies with the test for sterility (2.6.1) except for the presence of mycobacteria.

Temperature stability. Maintain samples of the freeze-dried product at 37 °C for 4 weeks. Determine the number of viable units in the heated product and in unheated product as described below. The number of viable units in the heated product is within the limits approved for the particular product but in any case not less than 20 per cent of that in unheated product.

Water. Not more than the limit approved for the particular product, determined by a suitable method.

ASSAY

Determine the number of viable units in the reconstituted product by viable count on solid medium using a method suitable for the product to be examined or by a suitable validated biochemical method. The number is within the range stated on the label. Determine the number of viable units in the comparison control in parallel.

LABELLING

The label states:

- the minimum and the maximum number of viable units per dose in the reconstituted product,
- that the product must be protected from direct sunlight.

01/2005:0163

BCG VACCINE, FREEZE-DRIED

*Vaccinum tuberculosis (BCG)
cryodesiccatum*

DEFINITION

Freeze-dried BCG vaccine is a preparation of live bacteria derived from a culture of the bacillus of Calmette and Guérin (*Mycobacterium bovis* BCG) whose capacity to protect against tuberculosis has been established.

PRODUCTION

GENERAL PROVISIONS

BCG vaccine shall be produced by a staff consisting of healthy persons who do not work with other infectious agents; in particular they shall not work with virulent strains of *Mycobacterium tuberculosis*, nor shall they be exposed to a known risk of tuberculosis infection. Staff are examined periodically for tuberculosis. BCG vaccine is susceptible to sunlight: the procedures for the preparation of the vaccine shall be designed so that all cultures and vaccines are protected from direct sunlight and from ultraviolet light at all stages of manufacture, testing and storage.

Production of the vaccine is based on a seed-lot system. The production method shall have been shown to yield consistently BCG vaccines that induce adequate sensitivity to tuberculin in man, that have acceptable protective potency in animals and are safe. The vaccine is prepared from cultures which are derived from the master seed lot by as few subcultures as possible and in any case not more than 8 subcultures. During the course of these subcultures the preparation is not freeze-dried more than once.

If a bioluminescence test or other biochemical method is used instead of viable count, the method is validated against the viable count for each stage of the process at which it is used.

BACTERIAL SEED LOTS

The strain used to establish the master seed lot is chosen for and maintained to preserve its characteristics, its capacity to sensitise man to tuberculin and to protect animals against tuberculosis, and its relative absence of pathogenicity for man and laboratory animals. The strain used shall be identified by historical records that include information on its origin and subsequent manipulation.

A suitable batch of vaccine is prepared from the first working seed lot and is reserved for use as the comparison vaccine. When a new working seed lot is established, a suitable test for delayed hypersensitivity in guinea-pigs is carried out on a batch of vaccine prepared from the new working seed lot; the vaccine is shown to be not significantly different in activity from the comparison vaccine. Antimicrobial agent sensitivity testing is also carried out.

Only a working seed lot that complies with the following requirements may be used for propagation.

Identification. The bacteria in the working seed lot are identified as *Mycobacterium bovis* BCG using microbiological techniques, which may be supplemented by molecular biology techniques (for example, nucleic acid amplification and restriction-fragment-length polymorphism).

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml for each medium. The working seed lot complies with the test for sterility except for the presence of mycobacteria.

Virulent mycobacteria. Examine the working seed lot as prescribed under Tests, using 10 guinea-pigs.

PROPAGATION AND HARVEST

The bacteria are grown in a suitable medium for not more than 21 days by surface or submerged culture. The culture medium does not contain substances known to cause toxic or allergic reactions in humans or to cause the bacteria to become virulent for guinea-pigs. The culture is harvested and suspended in a sterile liquid medium that protects the viability of the vaccine as determined by a suitable method of viable count.

FINAL BULK VACCINE

The final bulk vaccine is prepared from a single harvest or by pooling a number of single harvests. A stabiliser may be added; if the stabiliser interferes with the determination of bacterial concentration in the final bulk vaccine, the determination is carried out before addition of the stabiliser.

Only final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml for each medium. The final bulk vaccine complies with the test for sterility except for the presence of mycobacteria.

Count of viable units. Determine the number of viable units per millilitre by viable count on solid medium using a method suitable for the vaccine to be examined or by a suitable biochemical method. Carry out the test in parallel on a reference preparation of the same strain.

Bacterial concentration. Determine the total bacterial concentration by a suitable method, either directly by determining the mass of the micro-organisms, or indirectly by an opacity method that has been calibrated in relation to the mass of the organisms; if the bacterial concentration is determined before addition of a stabiliser, the concentration in the final bulk vaccine is established by calculation. The total bacterial concentration is within the limits approved for the particular product.

The ratio of the count of viable units to the total bacterial concentration is not less than that approved for the particular product.

FINAL LOT

The final bulk vaccine is distributed into sterile containers and freeze-dried to a moisture content favourable to the stability of the vaccine; the containers are closed either under vacuum or under an inert gas.

Except where the filled and closed containers are stored at a temperature of -20°C or lower, the expiry date is not later than 4 years from the date of harvest.

Only a final lot that complies with the following requirement for count of viable units and with each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the test for virulent mycobacteria has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot. Provided the test for excessive dermal reactivity has been carried out with satisfactory results on the working seed lot and on 5 consecutive final lots produced from it, the test may be omitted on the final lot.

Count of viable units. Determine the number of viable units per millilitre of the reconstituted vaccine by viable count on solid medium using a method suitable for the vaccine to be examined or by a suitable biochemical method. The ratio of the count of viable units after freeze-drying to that before is not less than that approved for the particular product.

IDENTIFICATION

BCG vaccine is identified by microscopic examination of the bacilli in stained smears demonstrating their acid-fast property and by the characteristic appearance of colonies grown on solid medium. Alternatively, molecular biology techniques (for example nucleic acid amplification) may be used.

TESTS

Virulent mycobacteria. Inject subcutaneously or intramuscularly into each of 6 guinea-pigs, each weighing 250-400 g and having received no treatment likely to interfere with the test, a quantity of vaccine equivalent to at least 50 human doses. Observe the animals for at least 42 days. At the end of this period, kill the guinea-pigs and examine by autopsy for signs of infection with tuberculosis, ignoring any minor reactions at the site of injection. Animals that die during the observation period are also examined for signs of tuberculosis. The vaccine complies with the test if none of the guinea-pigs shows signs of tuberculosis and if not more than 1 animal dies during the observation period. If 2 animals die during this period and autopsy does not reveal signs of tuberculosis repeat the test on 6 other guinea-pigs. The vaccine complies with the test if not more than 1 animal dies during the 42 days following the injection and autopsy does not reveal any sign of tuberculosis.

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (2.6.1) except for the presence of mycobacteria.

Excessive dermal reactivity. Use 6 healthy, white or pale-coloured guinea-pigs, each weighing not less than 250 g and having received no treatment likely to interfere with the test. Inject intradermally into each guinea-pig, according to a randomised plan, 0.1 ml of the reconstituted vaccine and of 2 tenfold serial dilutions of the vaccine and identical doses of the comparison vaccine. Observe the lesions formed at the site of the injection for 4 weeks. The vaccine complies with the test if the reaction it produces is not markedly different from that produced by the comparison vaccine.

Temperature stability. Maintain samples of the freeze-dried vaccine at 37°C for 4 weeks. Determine the number of viable units in the heated vaccine and in unheated vaccine as described below. The number of viable units in the heated vaccine is not less than 20 per cent that in unheated vaccine.

Water. Not more than the limit approved for the particular product, determined by a suitable method.

ASSAY

Determine the number of viable units in the reconstituted vaccine by viable count on solid medium using a method suitable for the vaccine to be examined or by a suitable validated biochemical method. The number is within the range stated on the label. Determine the number of viable units in the comparison vaccine in parallel.

LABELLING

The label states:

- the minimum and maximum number of viable units per millilitre in the reconstituted vaccine,
- that the vaccine must be protected from direct sunlight.

01/2005:0154

CHOLERA VACCINE**Vaccinum cholerae****DEFINITION**

Cholera vaccine is a homogeneous suspension of a suitable strain or strains of *Vibrio cholerae* containing not less than 8×10^9 bacteria in each human dose. The human dose does not exceed 1.0 ml.

PRODUCTION

The vaccine is prepared using a seed-lot system. The vaccine consists of a mixture of equal parts of vaccines prepared from smooth strains of the 2 main serological types, Inaba and Ogawa. These may be of the classical biotype with or without the El-Tor biotype. A single strain or several strains of each type may be included. All strains must contain, in addition to their type O antigens, the heat-stable O antigen common to Inaba and Ogawa. If more than one strain each of Inaba and Ogawa are used, these may be selected so as to contain other O antigens in addition. The World Health Organisation recommends new strains which may be used if necessary, in accordance with the regulations in force in the signatory States of the Convention on the Elaboration of a European Pharmacopoeia. In order to comply with the requirements for vaccination certificates required for international travel, the vaccine must contain not less than 8×10^9 organisms of the classical biotype. Each strain is grown separately. The bacteria are inactivated either by heating the suspensions (for example, at 56 °C for 1 h) or by treatment with formaldehyde or phenol or by a combination of the physical and chemical methods.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9) modified as follows: inject 0.5 ml of the vaccine into each mouse and 1.0 ml into each guinea pig.

IDENTIFICATION

It is identified by specific agglutination tests.

TESTS

Phenol (2.5.15). If phenol has been used in the preparation, the concentration is not more than 5 g/l.

Antibody production. Test the ability of the vaccine to induce antibodies (such as agglutinating, vibriocidal or haemagglutinating antibodies) in the guinea-pig, the rabbit or the mouse. Administer the vaccine to a group of at least 6 animals. At the end of the interval of time necessary for maximum antibody formation, determined in preliminary tests, collect sera from the animals and titrate them individually for the appropriate antibody using a suitable method. The vaccine to be examined passes the test if each serotype has elicited a significant antibody response.

Sterility (2.6.1). It complies with the test for sterility.

LABELLING

The label states:

- the method used to inactivate the bacteria,
- the number of bacteria in each human dose.

01/2005:0155

CHOLERA VACCINE, FREEZE-DRIED

Vaccinum cholerae cryodesiccatum

DEFINITION

Freeze-dried cholera vaccine is a preparation of a suitable strain or strains of *Vibrio cholerae*. The vaccine is reconstituted as stated on the label to give a uniform

suspension containing not less than 8×10^9 bacteria in each human dose. The human dose does not exceed 1.0 ml of the reconstituted vaccine.

PRODUCTION

The vaccine is prepared using a seed-lot system. The vaccine consists of a mixture of equal parts of vaccines prepared from smooth strains of the 2 main serological types, Inaba and Ogawa. These may be of the classical biotype with or without the El-Tor biotype. A single strain or several strains of each type may be included. All strains must contain, in addition to their type O antigens, the heat-stable O antigen common to Inaba and Ogawa. If more than one strain each of Inaba and Ogawa are used, these may be selected so as to contain other O antigens in addition. The World Health Organisation recommends new strains which may be used if necessary in accordance with the regulations in force in the signatory States of the Convention on the Elaboration of a European Pharmacopoeia. In order to comply with the requirements for vaccination certificates required for international travel, the vaccine must contain not less than 8×10^9 organisms of the classical biotype. Each strain is grown separately. The bacteria are inactivated either by heating the suspensions (for example, at 56 °C for 1 h) or by treatment with formaldehyde or by a combination of the physical and chemical methods. Phenol is not used in the preparation. The vaccine is distributed into sterile containers and freeze-dried to a moisture content favourable to the stability of the vaccine. The containers are then closed so as to exclude contamination.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9) modified as follows: inject 0.5 ml of the vaccine into each mouse and 1.0 ml into each guinea pig.

IDENTIFICATION

The vaccine reconstituted as stated on the label is identified by specific agglutination tests.

TESTS

Phenol (2.5.15). If phenol has been used in the preparation, the concentration is not more than 5 g/l.

Antibody production. Test the ability of the vaccine to induce antibodies (such as agglutinating, vibriocidal or haemagglutinating antibodies) in the guinea-pig, the rabbit or the mouse. Administer the reconstituted vaccine to a group of at least 6 animals. At the end of the interval of time necessary for maximum antibody formation, determined in preliminary tests, collect sera from the animals and titrate them individually for the appropriate antibody using a suitable method. The vaccine to be examined passes the test if each serotype has elicited a significant antibody response.

Sterility (2.6.1). The reconstituted vaccine complies with the test for sterility.

LABELLING

The label states:

- the method used to inactivate the bacteria,
- the number of bacteria in each human dose.

01/2005:0444 IDENTIFICATION

DIPHTHERIA AND TETANUS VACCINE (ADSORBED)

Vaccinum diphtheriae et tetani adsorbatum

DEFINITION

Diphtheria and tetanus vaccine (adsorbed) is a preparation of diphtheria formol toxoid and tetanus formol toxoid with a mineral adsorbent. The formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani*, respectively.

PRODUCTION

GENERAL PROVISIONS

Specific toxicity of the diphtheria and tetanus components.

The production method is validated to demonstrate that the product, if tested, would comply with the following test: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 42 days of the injection any of the animals shows signs of or dies from diphtheria toxæmia or tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

BULK PURIFIED DIPHTHERIA AND TETANUS TOXOIDS

The bulk purified diphtheria and tetanus toxoids are prepared as described in the monographs on *Diphtheria vaccine (adsorbed)* (0443) and *Tetanus vaccine (adsorbed)* (0452) and comply with the requirements prescribed therein.

FINAL BULK VACCINE

The final bulk vaccine is prepared by adsorption of suitable quantities of bulk purified diphtheria toxoid and tetanus toxoid onto a mineral carrier such as hydrated aluminium phosphate or aluminium hydroxide; the resulting mixture is approximately isotonic with blood. Suitable antimicrobial preservatives may be added. Certain antimicrobial preservatives, particularly those of the phenolic type, adversely affect the antigenic activity and must not be used. Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the test for antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the free formaldehyde content has been determined on the bulk purified antigens or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

- A. Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.
- B. Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained as described in identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.

TESTS

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 30 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose.

LABELLING

The label states:

- the minimum number of International Units of each component per single human dose,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:0647

DIPHTHERIA AND TETANUS VACCINE (ADSORBED) FOR ADULTS AND ADOLESCENTS

Vaccinum diphtheriae et tetani adulti et adulescentis adsorbatum

DEFINITION

Diphtheria and tetanus vaccine (adsorbed) for adults and adolescents is a preparation of diphtheria formol toxoid and tetanus formol toxoid with a mineral adsorbent. The

formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani*, respectively. It shall have been demonstrated to the competent authority that the quantity of diphtheria toxoid used does not produce adverse reactions in subjects from the age groups for which the vaccine is intended.

PRODUCTION

GENERAL PROVISIONS

Specific toxicity of the diphtheria and tetanus components.

The production method is validated to demonstrate that the product, if tested, would comply with the following test: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 42 days of the injection any of the animals shows signs of or dies from diphtheria toxæmia or tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

BULK PURIFIED DIPHTHERIA TOXOID AND TETANUS TOXOIDS

The bulk purified diphtheria and tetanus toxoids are prepared as described in the monographs on *Diphtheria vaccine (adsorbed)* (0443) and *Tetanus vaccine (adsorbed)* (0452) and comply with the requirements prescribed therein.

FINAL BULK VACCINE

The vaccine is prepared by adsorption of suitable quantities of bulk purified diphtheria toxoid and tetanus toxoid onto a mineral carrier such as hydrated aluminium phosphate or aluminium hydroxide; the resulting mixture is approximately isotonic with blood. Suitable antimicrobial preservatives may be added. Certain antimicrobial preservatives, particularly those of the phenolic type, adversely affect the antigenic activity and must not be used.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the test for antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the free formaldehyde content has been determined on the bulk purified toxoids or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

IDENTIFICATION

- A. Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate. If a satisfactory result is not obtained with a vaccine adsorbed on aluminium hydroxide, carry out the test as follows. Centrifuge 15 ml of the vaccine to be examined and suspend the residue in 5 ml of a freshly prepared mixture of 1 volume of a 56 g/l solution of *sodium edetate R* and 49 volumes of a 90 g/l solution of *disodium hydrogen phosphate R*. Maintain at 37 °C for not less than 6 h and centrifuge. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.
- B. Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained during identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.

TESTS

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 2 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 20 IU per single human dose.

LABELLING

The label states:

- the minimum number of International Units of each component per single human dose,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:2062 FINAL BULK VACCINE

DIPHTHERIA, TETANUS AND HEPATITIS B (rDNA) VACCINE (ADSORBED)

Vaccinum diphtheriae, tetani et
hepatitidis B (ADNr) adsorbatum

DEFINITION

Diphtheria, tetanus and hepatitis B (rDNA) vaccine (adsorbed) is a combined vaccine composed of: diphtheria formol toxoid; tetanus formol toxoid; hepatitis B surface antigen (HBsAg); a mineral adsorbent such as aluminium hydroxide or hydrated aluminium phosphate.

The formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani*, respectively.

HBsAg is a component protein of hepatitis B virus; the antigen is obtained by recombinant DNA technology.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

The content of bacterial endotoxins (2.6.14) in the bulk purified diphtheria toxoid and tetanus toxoid is determined to monitor the purification procedure and to limit the amount in the final vaccine. For each component, the content of bacterial endotoxins is less than the limit approved for the particular vaccine and in any case the contents are such that the final vaccine contains less than 100 IU per single human dose.

Reference vaccine(s). Provided valid assays can be performed, monocomponent reference vaccines may be used for the assays on the combined vaccine. If this is not possible because of interaction between the components of the combined vaccine or because of the difference in composition between monocomponent reference vaccine and the test vaccine, a batch of combined vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine may be stabilised by a method that has been shown to have no effect on the assay procedure.

Specific toxicity of the diphtheria and tetanus components.

The production method is validated to demonstrate that the product, if tested, would comply with the following test: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 42 days of the injection any of the animals shows signs of or dies from diphtheria toxæmia or tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

PRODUCTION OF THE COMPONENTS

The production of the components complies with the requirements of the monographs on *Diphtheria vaccine (adsorbed)* (0443), *Tetanus vaccine (adsorbed)* (0452) and *Hepatitis B vaccine (rDNA)* (1056).

FINAL BULK VACCINE

The final bulk vaccine is prepared by adsorption, separately or together, of suitable quantities of bulk purified diphtheria toxoid, tetanus toxoid and HBsAg onto a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate. Suitable antimicrobial preservatives may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to the test for osmolality and with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided the test for antimicrobial preservative and the assays for the diphtheria and tetanus components have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the content of free formaldehyde has been determined on the bulk purified antigens or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

If an *in vivo* assay is used for the hepatitis B component, provided it has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Osmolality (2.2.35). The osmolality of the vaccine is within the limits approved for the particular preparation.

IDENTIFICATION

- Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.
- Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained during identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.
- The assay or, where applicable, the electrophoretic profile, serves also to identify the hepatitis B component of the vaccine.

TESTS

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). It complies with the test for sterility.

Pyrogens (2.6.8). It complies with the test for pyrogens. Inject the equivalent of 1 human dose into each rabbit.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 30 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose.

Hepatitis B component. It complies with the assay of hepatitis B vaccine (2.7.15).

LABELLING

The label states:

- the minimum number of International Units of diphtheria and tetanus toxoid per single human dose,
- the amount of HBsAg per single human dose,
- the type of cells used for production of the HBsAg component,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:1931

DIPHTHERIA, TETANUS AND PERTUSSIS (ACELLULAR, COMPONENT) VACCINE (ADSORBED)

Vaccinum diphtheriae, tetani et pertussis
sine cellulis ex elementis praeparatum
adsorbatum

DEFINITION

Diphtheria, tetanus and pertussis (acellular, component) vaccine (adsorbed) is a combined vaccine composed of: diphtheria formol toxoid; tetanus formol toxoid; individually purified antigenic components of *Bordetella pertussis*; a mineral adsorbent such as aluminium hydroxide or hydrated aluminium phosphate.

The formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani*, respectively.

The vaccine contains either pertussis toxoid or a pertussis-toxin-like protein free from toxic properties, produced by expression of a genetically modified form of the corresponding gene. Pertussis toxoid is prepared from pertussis toxin by a method that renders the latter harmless while maintaining adequate immunogenic properties and avoiding reversion to toxin. The vaccine may also contain filamentous haemagglutinin, pertactin (a 69 kDa outer-membrane protein) and other defined components of *B. pertussis* such as fimbrial-2 and fimbrial-3 antigens. The latter 2 antigens may be copurified. The antigenic composition and characteristics are based on evidence of protection and freedom from unexpected reactions in the target group for which the vaccine is intended.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

The content of bacterial endotoxins (2.6.14) in the bulk purified diphtheria toxoid, tetanus toxoid and pertussis components is determined to monitor the purification procedure and to limit the amount in the final vaccine. For each component, the content of bacterial endotoxins is less than the limit approved for the particular vaccine and, in any case, the contents are such that the final vaccine contains less than 100 IU per single human dose.

Reference vaccine(s). Provided valid assays can be performed, monocomponent reference vaccines may be used for the assays on the combined vaccine. If this is not possible because of interaction between the components of the combined vaccine or because of the difference in composition between monocomponent reference vaccine and the test vaccine, a batch of combined vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine may be stabilised by a method that has been shown to have no effect on the assay procedure.

PRODUCTION OF THE COMPONENTS

The production of the components complies with the requirements of the monographs on *Diphtheria vaccine (adsorbed)* (0443), *Tetanus vaccine (adsorbed)* (0452) and *Pertussis vaccine (acellular, component, adsorbed)* (1356).

FINAL BULK VACCINE

The final bulk vaccine is prepared by adsorption of suitable quantities of bulk purified diphtheria toxoid, tetanus toxoid and pertussis components separately or together onto a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate. Suitable antimicrobial preservatives may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to the test for osmolality and with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided the tests for absence of residual pertussis toxin, irreversibility of pertussis toxoid, free formaldehyde and antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Osmolality (2.2.35). The osmolality of the vaccine is within the limits approved for the particular preparation.

IDENTIFICATION

- Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for

about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.

- B. Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained as described in identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.
- C. The pertussis components are identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained as described in identification test A reacts with specific antisera to the pertussis components of the vaccine.

TESTS

Absence of residual pertussis toxin and irreversibility of pertussis toxoid. *This test is not necessary for the product obtained by genetic modification.* Use 3 groups each of not fewer than 5 histamine-sensitive mice. Inject intraperitoneally into the first group twice the single human dose of the vaccine stored at 2-8 °C. Inject intraperitoneally into the second group twice the single human dose of the vaccine incubated at 37 °C for 4 weeks. Inject diluent into the third group of mice. After 5 days, inject into each mouse 2 mg of histamine base intraperitoneally in a volume not exceeding 0.5 ml and observe for 24 h. The test is invalid if 1 or more control mice die following histamine challenge. The vaccine complies with the test if no animal in the first or second group dies following histamine challenge. If 1 mouse dies in either or both of the first and second groups, the test may be repeated with the same number of mice or with a greater number and the results of valid tests combined; the vaccine complies with the test if, in both of the groups given the vaccine, not more than 5 per cent of the total number of mice die following histamine challenge.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject intravenously threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than the minimum potency stated on the label.

Unless otherwise justified and authorised, the minimum potency stated on the label is 30 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8). The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose.

Pertussis component. The vaccine complies with the assay of pertussis vaccine (acellular) (2.7.16).

LABELLING

The label states:

- the minimum number of International Units of diphtheria and tetanus toxoid per single human dose,
- the names and amounts of the pertussis components per single human dose,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen,
- where applicable, that the vaccine contains a pertussis toxin-like protein produced by genetic modification.

01/2005:0445

DIPHTHERIA, TETANUS AND PERTUSSIS VACCINE (ADSORBED)

Vaccinum diphtheriae, tetani et pertussis adsorbatum

DEFINITION

Diphtheria, tetanus and pertussis vaccine (adsorbed) is a preparation of diphtheria formol toxoid and tetanus formol toxoid with a mineral adsorbent to which a suspension of inactivated *Bordetella pertussis* has been added. The formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani*, respectively.

PRODUCTION

GENERAL PROVISIONS

Specific toxicity of the diphtheria and tetanus components.

The production method is validated to demonstrate that the product, if tested, would comply with the following test: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 42 days of the injection any of the animals shows signs of or dies from diphtheria toxæmia or tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

BULK PURIFIED DIPHTHERIA AND TETANUS TOXOIDS, BULK INACTIVATED B. PERTUSSIS SUSPENSION

The bulk purified diphtheria and tetanus toxoids and the inactivated *B. pertussis* suspension are prepared as described in the monographs on *Diphtheria vaccine (adsorbed)* (0443), *Tetanus vaccine (adsorbed)* (0452) and *Pertussis vaccine (adsorbed)* (0161), respectively, and comply with the requirements prescribed therein.

FINAL BULK VACCINE

The final bulk vaccine is prepared by adsorption of suitable quantities of bulk purified diphtheria toxoid and tetanus toxoid onto a mineral carrier such as hydrated aluminium

phosphate or aluminium hydroxide and admixture of an appropriate quantity of a suspension of inactivated *B. pertussis*; the resulting mixture is approximately isotonic with blood. The *B. pertussis* concentration of the final bulk vaccine does not exceed that corresponding to an opacity of 20 IU per single human dose. If 2 or more strains of *B. pertussis* are used, the composition of consecutive lots of the final bulk vaccine shall be consistent with respect to the proportion of each strain as measured in opacity units. Suitable antimicrobial preservatives may be added to the bulk vaccine. Certain antimicrobial preservatives, particularly those of the phenolic type, adversely affect the antigenic activity and must not be used.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the tests for specific toxicity of the pertussis component, antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the free formaldehyde content has been determined on the bulk purified antigens or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

IDENTIFICATION

- Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained; reserve the precipitate for identification test C. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.
- Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained during identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.
- Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge to obtain a bacterial precipitate. Other suitable methods for separating the bacteria from the adsorbent may also be used. Identify pertussis vaccine by agglutination of the bacteria from the resuspended precipitate by antisera specific to *B. pertussis* or by the assay.

TESTS

Specific toxicity of the pertussis component. Use not fewer than 5 mice each weighing 14 g to 16 g for the vaccine group and for the saline control. Use mice of the same sex

or distribute males and females equally between the groups. Allow the animals access to food and water for at least 2 h before injection and during the test. Inject each mouse of the vaccine group intraperitoneally with 0.5 ml, containing a quantity of the vaccine equivalent to not less than half the single human dose. Inject each mouse of the control group with 0.5 ml of a 9 g/l sterile solution of *sodium chloride R*, preferably containing the same amount of antimicrobial preservative as that injected with the vaccine. Weigh the groups of mice immediately before the injection and 72 h and 7 days after the injection. The vaccine complies with the test if: (a) at the end of 72 h the total mass of the group of vaccinated mice is not less than that preceding the injection; (b) at the end of 7 days the average increase in mass per vaccinated mouse is not less than 60 per cent of that per control mouse; and (c) not more than 5 per cent of the vaccinated mice die during the test. The test may be repeated and the results of the tests combined.

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 30 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8).

If the test is carried out in guinea-pigs, the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose; if the test is carried out in mice, the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 60 IU per single human dose.

Pertussis component. Carry out the assay of pertussis vaccine (2.7.7).

The estimated potency is not less than 4 IU per single human dose and the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 2 IU per single human dose.

LABELLING

The label states:

- the minimum number of International Units of each component per single human dose,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:1932

DIPHTHERIA, TETANUS, PERTUSSIS (ACELLULAR, COMPONENT) AND HAEMOPHILUS TYPE b CONJUGATE VACCINE (ADSORBED)

Vaccinum diphtheriae, tetani, pertussis
sine cellulis ex elementis praeparatum
et haemophili stirpe b coniugatum
adsorbatum

DEFINITION

Diphtheria, tetanus, pertussis (acellular, component) and haemophilus type b conjugate vaccine (adsorbed) is a combined vaccine composed of: diphtheria formol toxoid; tetanus formol toxoid; individually purified antigenic components of *Bordetella pertussis*; polyribosylribitol phosphate (PRP) covalently bound to a carrier protein; a mineral absorbent such as aluminium hydroxide or hydrated aluminium phosphate. The product may be presented with the haemophilus type b component in a separate container, the contents of which are mixed with the other components immediately before use.

The formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani* respectively.

The vaccine contains either pertussis toxoid or a pertussis-toxin-like protein free from toxic properties produced by expression of a genetically modified form of the corresponding gene. Pertussis toxoid is prepared from pertussis toxin by a method that renders the toxin harmless while maintaining adequate immunogenic properties and avoiding reversion to toxin. The acellular pertussis component may also contain filamentous haemagglutinin, pertactin (a 69 kDa outer-membrane protein) and other defined components of *B. pertussis* such as fimbrial-2 and fimbrial-3 antigens. The latter 2 antigens may be copurified. The antigenic composition and characteristics are based on evidence of protection and freedom from unexpected reactions in the target group for which the vaccine is intended.

PRP is a linear copolymer composed of repeated units of 3-β-D-ribofuranosyl-(1→1)-ribitol-5-phosphate $[(C_{10}H_{19}O_{12}P)_n]$, with a defined molecular size and derived from a suitable strain of *Haemophilus influenzae* type b. The carrier protein, when conjugated to PRP, is capable of inducing a T-cell-dependent B-cell immune response to the polysaccharide.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

If the vaccine is presented with the haemophilus component in a separate vial, as part of consistency studies the assays of the diphtheria, tetanus and pertussis components are carried out on a suitable number of batches of vaccine reconstituted as for use. For subsequent routine control, the assays of these components may be carried out without mixing with the haemophilus component.

The content of bacterial endotoxins (2.6.14) in bulk purified diphtheria toxoid, tetanus toxoid, pertussis components and PRP conjugate is determined to monitor the purification procedure and to limit the amount in the final vaccine. For each component, the content of bacterial endotoxins is less than the limit approved for the particular vaccine; if the vaccine is presented with the haemophilus component in a separate container, the contents of the diphtheria, tetanus and pertussis antigens are in any case such that the final vial for these components contains less than 100 IU per single human dose.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

During development studies and wherever revalidation is necessary, it shall be demonstrated by tests in animals that the vaccine induces a T-cell dependent B-cell immune response to PRP.

Reference vaccine(s). Provided valid assays can be performed, monocomponent reference vaccines may be used for the assays on the combined vaccine. If this is not possible because of interaction between the components of the combined vaccine or because of the difference in composition between monocomponent reference vaccine and the test vaccine, a batch of combined vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine may be stabilised by a method that has been shown to have no effect on the assay procedure.

PRODUCTION OF THE COMPONENTS

The production of the components complies with the requirements of the monographs on *Diphtheria vaccine (adsorbed)* (0443), *Tetanus vaccine (adsorbed)* (0452), *Pertussis vaccine (acellular, component, adsorbed)* (1356) and *Haemophilus type b conjugate vaccine* (1219).

FINAL BULK VACCINE

Different methods of preparation may be used: a final bulk vaccine may be prepared by adsorption, separately or together, of suitable quantities of bulk purified diphtheria toxoid, tetanus toxoid, acellular pertussis components and PRP conjugate onto a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate; or 2 final bulks may be prepared and filled separately, one containing the diphtheria, tetanus and pertussis components, the other the haemophilus component, which may be freeze-dried. Suitable antimicrobial preservatives may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to the test for osmolality shown below and with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided the tests for absence of residual pertussis toxin, irreversibility of pertussis toxoid and antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the free formaldehyde content has been determined on the bulk purified antigens or the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

Osmolality. (2.2.35). The osmolality of the vaccine, reconstituted where applicable, is within the limits approved for the particular preparation.

pH (2.2.3). The pH of the vaccine, reconstituted if necessary, is within the range approved for the particular product.

Free PRP. Unbound PRP is determined after removal of the conjugate, for example by anion-exchange, size-exclusion or hydrophobic chromatography, ultrafiltration or other validated methods. The amount of free PRP is not greater than that approved for the particular product.

IDENTIFICATION

If the vaccine is presented with the haemophilus component in a separate vial: identification tests A, B and C are carried out using the vial containing the diphtheria, tetanus and pertussis components; identification test D is carried out on the vial containing the haemophilus components.

- A. Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.
- B. Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained as described in identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.
- C. The pertussis components are identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained as described in identification test A reacts with a specific antisera to the pertussis components of the vaccine.
- D. The haemophilus component is identified by a suitable immunochemical method (2.7.1) for PRP.

TESTS

If the product is presented with the haemophilus component in a separate container: the tests for absence of residual pertussis toxin, irreversibility of pertussis toxoid, aluminium, free formaldehyde, antimicrobial preservative and sterility are carried out on the container with the diphtheria, tetanus and pertussis components; the tests for PRP content, water (where applicable), sterility and pyrogens are carried out on the container with the haemophilus component.

If the haemophilus component is freeze-dried, some tests may be carried out on the freeze-dried product rather than on the bulk conjugate where the freeze-drying process may affect the component to be tested.

Absence of residual pertussis toxin and irreversibility of pertussis toxoid. This test is not necessary for the product obtained by genetic modification. Use 3 groups each of not fewer than 5 histamine-sensitive mice. Inject intraperitoneally into the first group twice the single human dose of the vaccine stored at 2–8 °C. Inject intraperitoneally into the second group twice the single human dose of the vaccine incubated at 37 °C for 4 weeks. Inject diluent into

the third group of mice. After 5 days, inject into each mouse 2 mg of histamine base intraperitoneally in a volume not exceeding 0.5 ml and observe for 24 h. The test is invalid if 1 or more control mice die following histamine challenge. The vaccine complies with the test if no animal in the first or second group dies following histamine challenge. If 1 mouse dies in either or both of the first and second groups, the test may be repeated with the same number of mice or with a greater number and the results of valid tests combined; the vaccine complies with the test if, in both of the groups given the vaccine, not more than 5 per cent of the total number of mice die following histamine challenge.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject intravenously threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

PRP: minimum 80 per cent of the amount of PRP stated on the label. PRP is determined either by assay of ribose (2.5.31) or phosphorus (2.5.18), by an immunochemical method (2.7.1) or by anion-exchange liquid chromatography (2.2.29) with pulsed-amperometric detection.

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Water (2.5.12): maximum 3.0 per cent for the freeze-dried haemophilus component.

Sterility (2.6.1). It complies with the test for sterility.

Pyrogens (2.6.8). It complies with the test for pyrogens. Inject per kilogram of the rabbit's mass a quantity of the vaccine equivalent to: 1 µg of PRP for a vaccine with diphtheria toxoid or CRM 197 diphtheria protein as carrier; 0.1 µg of PRP for a vaccine with tetanus toxoid as carrier; 0.025 µg of PRP for a vaccine with OMP as carrier.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than the minimum potency stated on the label.

Unless otherwise justified and authorised, the minimum potency stated on the label is 30 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose.

Pertussis component. The vaccine complies with the assay of pertussis vaccine (acellular) (2.7.16).

LABELLING

The label states:

- the minimum number of International Units of diphtheria and tetanus toxoid per single human dose,

- the names and amounts of the pertussis components per single human dose,
- the number of micrograms of PRP per single human dose,
- the type and nominal amount of carrier protein per single human dose,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen,
- where applicable, that the vaccine contains a pertussis toxin-like protein produced by genetic modification.

01/2005:1933

DIPHTHERIA, TETANUS, PERTUSSIS (ACELLULAR, COMPONENT) AND HEPATITIS B (rDNA) VACCINE (ADSORBED)

Vaccinum diphtheriae, tetani, pertussis
sine cellulis ex elementis praeparatum et
hepatitidis B (ADNr) adsorbatum

DEFINITION

Diphtheria, tetanus, pertussis (acellular, component) and hepatitis B (rDNA) vaccine (adsorbed) is a combined vaccine composed of: diphtheria formol toxoid; tetanus formol toxoid; individually purified antigenic components of *Bordetella pertussis*; hepatitis B surface antigen; a mineral adsorbent such as aluminium hydroxide or hydrated aluminium phosphate.

The formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani*, respectively.

The vaccine contains either pertussis toxoid or a pertussis-toxin-like protein free from toxic properties, produced by expression of a genetically modified form of the corresponding gene. Pertussis toxoid is prepared from pertussis toxin by a method that renders the latter harmless while maintaining adequate immunogenic properties and avoiding reversion to toxin. The vaccine may also contain filamentous haemagglutinin, pertactin (a 69 kDa outer-membrane protein) and other defined components of *B. pertussis* such as fimbrial-2 and fimbrial-3 antigens. The latter 2 antigens may be copurified. The antigenic composition and characteristics are based on evidence of protection and freedom from unexpected reactions in the target group for which the vaccine is intended.

Hepatitis B surface antigen is a component protein of hepatitis B virus; the antigen is obtained by recombinant DNA technology.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

The content of bacterial endotoxins (2.6.14) in the bulk purified diphtheria toxoid, tetanus toxoid and pertussis components is determined to monitor the purification procedure and to limit the amount in the final vaccine. For each component, the content of bacterial endotoxins is less than the limit approved for the particular vaccine.

Reference vaccine(s). Provided valid assays can be performed, monocomponent reference vaccines may be used for the assays on the combined vaccine. If this is not possible because of interaction between the components of the combined vaccine or because of the difference in composition between monocomponent reference vaccine and the test vaccine, a batch of combined vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine may be stabilised by a method that has been shown to have no effect on the assay procedure.

PRODUCTION OF THE COMPONENTS

The production of the components complies with the requirements of the monographs on *Diphtheria vaccine (adsorbed)* (0443), *Tetanus vaccine (adsorbed)* (0452), *Pertussis vaccine (acellular, component, adsorbed)* (1356) and *Hepatitis B vaccine (rDNA)* (1056).

FINAL BULK VACCINE

The final bulk vaccine is prepared by adsorption, separately or together, of suitable quantities of bulk purified diphtheria toxoid, tetanus toxoid, acellular pertussis components and hepatitis B surface antigen onto a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate. Suitable antimicrobial preservatives may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to the test for osmolality and with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided the tests for absence of residual pertussis toxin, irreversibility of pertussis toxoid and antimicrobial preservative and the assays for the diphtheria, tetanus and pertussis components have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the content of free formaldehyde has been determined on the bulk purified antigens or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

If an *in vivo* assay is used for the hepatitis B component, provided it has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Osmolality (2.2.35). The osmolality of the vaccine is within the limits approved for the particular preparation.

IDENTIFICATION

- Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.

- B. Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained as described in identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.
- C. The pertussis components are identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained as described in identification test A reacts with a specific antisera to the pertussis components of the vaccine.
- D. The assay or, where applicable, the electrophoretic profile, serves also to identify the hepatitis B component of the vaccine.

TESTS

Absence of residual pertussis toxin and irreversibility of pertussis toxoid. *This test is not necessary for the product obtained by genetic modification.* Use 3 groups each of not fewer than 5 histamine-sensitive mice. Inject intraperitoneally into the first group twice the single human dose of the vaccine stored at 2–8 °C. Inject intraperitoneally into the second group twice the single human dose of the vaccine incubated at 37 °C for 4 weeks. Inject diluent into the third group of mice. After 5 days, inject into each mouse 2 mg of histamine base intraperitoneally in a volume not exceeding 0.5 ml and observe for 24 h. The test is invalid if 1 or more control mice die following histamine challenge. The vaccine complies with the test if no animal in the first or second group dies following histamine challenge. If 1 mouse dies in either or both of the first and second groups, the test may be repeated with the same number of mice or with a greater number and the results of valid tests combined; the vaccine complies with the test if, in both of the groups given the vaccine, not more than 5 per cent of the total number of mice die following histamine challenge.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject intravenously threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

Pyrogens (2.6.8). The vaccine complies with the test for pyrogens. Inject the equivalent of 1 human dose into each rabbit.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than the minimum potency stated on the label.

Unless otherwise justified and authorised, the minimum potency stated on the label is 30 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8). The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose.

Pertussis component. The vaccine complies with the assay of pertussis vaccine (acellular) (2.7.16).

Hepatitis B component. The vaccine complies with the assay of hepatitis B vaccine (2.7.15).

LABELLING

The label states:

- the minimum number of International Units of diphtheria and tetanus toxoid per single human dose,
- the names and amounts of the pertussis components per single human dose,
- the amount of HBsAg per single human dose,
- the type of cells used for production of the hepatitis B component,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen,
- where applicable, that the vaccine contains a pertussis toxin-like protein produced by genetic modification.

01/2005:1934

DIPHTHERIA, TETANUS, PERTUSSIS (ACELLULAR, COMPONENT) AND POLIOMYELITIS (INACTIVATED) VACCINE (ADSORBED)

Vaccinum diphtheriae, tetani, pertussis
sine cellulis ex elementis praeparatum et
poliomyelitis inactivatum adsorbatum

DEFINITION

Diphtheria, tetanus, pertussis (acellular, component) and poliomyelitis (inactivated) vaccine (adsorbed) is a combined vaccine containing: diphtheria formol toxoid; tetanus formol toxoid; individually purified antigenic components of *Bordetella pertussis*; suitable strains of human polioviruses 1, 2 and 3 grown in suitable cell cultures and inactivated by a validated method; a mineral adsorbent such as aluminium hydroxide or hydrated aluminium phosphate.

The formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani* respectively.

The vaccine contains either pertussis toxoid or a pertussis-toxin-like protein free from toxic properties produced by expression of a genetically modified form of the corresponding gene. Pertussis toxoid is prepared from

pertussis toxin by a method that renders the toxin harmless while maintaining adequate immunogenic properties and avoiding reversion to toxin. The vaccine may also contain filamentous haemagglutinin, pertactin (a 69 kDa outer-membrane protein) and other defined components of *B. pertussis* such as fimbrial-2 and fimbrial-3 antigens. The latter 2 antigens may be copurified. The antigenic composition and characteristics are based on evidence of protection and freedom from unexpected reactions in the target group for which the vaccine is intended.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

The content of bacterial endotoxins (2.6.14) in bulk purified diphtheria toxoid, tetanus toxoid, pertussis components and purified, inactivated monovalent poliovirus harvests is determined to monitor the purification procedure and to limit the amount in the final vaccine. For each component, the content of bacterial endotoxins is less than the limit approved for the particular vaccine and, in any case, the contents are such that the final vaccine contains less than 100 IU per single human dose.

Reference vaccine(s). Provided valid assays can be performed, monocomponent reference vaccines may be used for the assays on the combined vaccine. If this is not possible because of interaction between the components of the combined vaccine or because of the difference in composition between monocomponent reference vaccine and the test vaccine, a batch of combined vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine may be stabilised by a method that has been shown to have no effect on the assay procedure.

PRODUCTION OF THE COMPONENTS

The production of the components complies with the requirements of the monographs on *Diphtheria vaccine (adsorbed)* (0443), *Tetanus vaccine (adsorbed)* (0452), *Pertussis vaccine (acellular, component, adsorbed)* (1356) and *Poliomyelitis vaccine (inactivated)* (0214).

FINAL BULK VACCINE

The final bulk vaccine is prepared by adsorption onto a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate, separately or together, of suitable quantities of bulk purified diphtheria toxoid, tetanus toxoid, acellular pertussis components and admixture of suitable quantities of purified monovalent harvests of human polioviruses 1, 2 and 3 or a suitable quantity of a trivalent pool of such purified monovalent harvests. Suitable antimicrobial preservatives may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Bovine serum albumin. Determined on the poliomyelitis components by a suitable immunochemical method (2.7.1) after virus harvest and before addition of the adsorbent in the preparation of the final bulk vaccine, the amount of bovine serum albumin is such that the content in the final vaccine will be not more than 50 ng per single human dose.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to the test for osmolality and with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided the tests for absence of residual pertussis toxin, irreversibility of pertussis toxoid and antimicrobial preservative and the assays for the diphtheria, tetanus and pertussis components have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the free formaldehyde content has been determined on the bulk purified antigens or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

Provided that the determination of D-antigen content has been carried out with satisfactory results during preparation of the final bulk before addition of the adsorbent, it may be omitted on the final lot.

Provided that the *in vivo* assay for the poliomyelitis component has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Osmolality (2.2.35). The osmolality of the vaccine is within the limits approved for the particular preparation.

IDENTIFICATION

- A. Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.
- B. Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained as described in identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.
- C. The pertussis components are identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained as described in identification test A reacts with a specific antisera to the pertussis components of the vaccine.
- D. The vaccine is shown to contain human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1) such as the determination of D-antigen by enzyme-linked immunosorbent assay (ELISA).

TESTS

Absence of residual pertussis toxin and irreversibility of pertussis toxoid. *This test is not necessary for the product obtained by genetic modification.* Use 3 groups each of not fewer than 5 histamine-sensitive mice. Inject intraperitoneally into the first group twice the single human dose of the vaccine stored at 2-8 °C. Inject intraperitoneally into the second group twice the single human dose of the vaccine incubated at 37 °C for 4 weeks. Inject diluent into

the third group of mice. After 5 days, inject into each mouse 2 mg of histamine base intraperitoneally in a volume not exceeding 0.5 ml and observe for 24 h. The test is invalid if 1 or more control mice die following histamine challenge. The vaccine complies with the test if no animal in the first or second group dies following histamine challenge. If 1 mouse dies in either or both of the first and second groups, the test may be repeated with the same number of mice or with a greater number and the results of valid tests combined; the vaccine complies with the test if, in both of the groups given the vaccine, not more than 5 per cent of the total number of mice die following histamine challenge.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject intravenously threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

Aluminium (2.5.13): maximum 1.25 mg per single human dose if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). It complies with the test for sterility.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than the minimum potency stated on the label.

Unless otherwise justified and authorised, the minimum potency stated on the label is 30 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose.

Pertussis component. The vaccine complies with the assay of pertussis vaccine (acellular) (2.7.16).

Poliomyelitis component

D-antigen content. As a measure of consistency of production, determine the D-antigen content for human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1) following desorption using a reference preparation calibrated in European Pharmacopoeia D-antigen units. For each type, the content, expressed with reference to the amount of D-antigen stated on the label, is within the limits approved for the particular product.

Poliomyelitis vaccine (inactivated) BRP is calibrated in European Pharmacopoeia units and intended for use in the assay of D-antigen. The European Pharmacopoeia unit and the International Unit are equivalent.

In vivo test. The vaccine complies with the *in vivo* assay of poliomyelitis vaccine (inactivated) (2.7.20).

LABELLING

The label states:

- the minimum number of International Units of diphtheria and tetanus toxoid per single human dose,
- the names and amounts of the pertussis components per single human dose,
- the types of poliovirus contained in the vaccine,
- the nominal amount of poliovirus of each type (1, 2 and 3), expressed in European Pharmacopoeia units of D-antigen, per single human dose,
- the type of cells used for production of the poliomyelitis component,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen,
- where applicable, that the vaccine contains a pertussis toxin-like protein produced by genetic modification.

01/2005:2067

DIPHTHERIA, TETANUS, PERTUSSIS (ACELLULAR, COMPONENT), HEPATITIS B (rDNA), POLIOMYELITIS (INACTIVATED) AND HAEMOPHILUS TYPE b CONJUGATE VACCINE (ADSORBED)

Vaccinum diphtheriae, tetani, pertussis
sine cellulis ex elementis praeparatum,
hepatitidis B (ADNr), poliomyelitidis
inactivatum et haemophili stirpe b
coniugatum adsorbatum

DEFINITION

Diphtheria, tetanus, pertussis (acellular, component), hepatitis B (rDNA), poliomyelitis (inactivated) and haemophilus type b conjugate vaccine (adsorbed) is a combined vaccine composed of: diphtheria formol toxoid; tetanus formol toxoid; individually purified antigenic components of *Bordetella pertussis*; hepatitis B surface antigen (HBsAg); human polioviruses 1, 2 and 3 grown in suitable cell cultures and inactivated by a suitable method; polyribosylribitol phosphate (PRP) covalently bound to a carrier protein. The antigens in the vaccine may be adsorbed on a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate. The product may be presented with the haemophilus component in a separate container, the contents of which are mixed with the other components immediately before or during use.

The formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani* respectively.

The vaccine contains either pertussis toxoid or a pertussis-toxin-like protein free from toxic properties produced by expression of a genetically modified form of the corresponding gene. Pertussis toxoid is prepared from pertussis toxin by a method that renders the toxin harmless while maintaining adequate immunogenic properties and avoiding reversion to toxin. The acellular pertussis component may also contain filamentous haemagglutinin,

pertactin (a 69 kDa outer-membrane protein) and other defined components of *B. pertussis* such as fimbrial-2 and fimbrial-3 antigens. The latter 2 antigens may be copurified. The antigenic composition and characteristics are based on evidence of protection and freedom from unexpected reactions in the target group for which the vaccine is intended.

Hepatitis B surface antigen is a component protein of hepatitis B virus; the antigen is obtained by recombinant DNA technology.

PRP is a linear copolymer composed of repeated units of 3-β-D-ribofuranosyl-(1 → 1)-ribitol-5-phosphate [(C₁₀H₁₉O₁₂P)_n], with a defined molecular size and derived from a suitable strain of *Haemophilus influenzae* type b. The carrier protein, when conjugated to PRP, is capable of inducing a T-cell-dependent B-cell immune response to the polysaccharide.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

If the vaccine is presented with the haemophilus component in a separate vial, as part of consistency studies the assays of the diphtheria, tetanus, pertussis, hepatitis B and poliomyelitis components are carried out on a suitable number of batches of vaccine reconstituted as for use. For subsequent routine control, the assays of these components may be carried out without mixing with the haemophilus component.

The content of bacterial endotoxins (2.6.14) in bulk purified diphtheria toxoid, bulk purified tetanus toxoid, bulk purified pertussis components, the hepatitis B surface antigen, the purified, inactivated monovalent poliovirus harvests and bulk PRP conjugate is determined to monitor the purification procedure and to limit the amount in the final vaccine. For each component, the content of bacterial endotoxins is not greater than the limit approved.

During development studies and wherever revalidation is necessary, a test for pyrogens in rabbits (2.6.8) is carried out by injection of a suitable dose of the final lot. The vaccine is shown to be acceptable with respect to absence of pyrogenic activity.

The production method is validated to demonstrate that the product, if tested, would comply with the following test for specific toxicity of the diphtheria and tetanus component: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 42 days of the injection any of the animals shows signs of or dies from diphtheria, toxæmia or tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

During development studies and wherever revalidation is necessary, it shall be demonstrated by tests in animals that the vaccine induces a T-cell-dependent B-cell immune response to PRP.

The stability of the final lot and relevant intermediates is evaluated using one or more indicator tests. For the haemophilus component, such tests may include determination of molecular size, determination of free PRP in the conjugate and kinetics of depolymerisation. Taking account of the results of the stability testing, release

requirements are set for these indicator tests to ensure that the vaccine will be satisfactory at the end of the period of validity.

Reference vaccine(s). Provided valid assays can be performed, monocomponent reference vaccines may be used for the assays on the combined vaccine. If this is not possible because of interaction between the components of the combined vaccine or because of the difference in composition between monocomponent reference vaccine and the test vaccine, a batch of combined vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine may be stabilised by a method that has been shown to have no effect on the assay procedure.

PRODUCTION OF THE COMPONENTS

The production of the components complies with the requirements of the monographs on *Diphtheria vaccine (adsorbed)* (0443), *Tetanus vaccine (adsorbed)* (0452), *Pertussis vaccine (acellular, component, adsorbed)* (1356), *Hepatitis B vaccine (rDNA)* (1056), *Poliomyelitis vaccine (inactivated)* (0214) and *Haemophilus type b conjugate vaccine* (1219).

FINAL BULKS

Vaccine with all components in the same container.

The final bulk is prepared by adsorption, separately or together, of suitable quantities of bulk purified diphtheria toxoid, bulk purified tetanus toxoid, bulk purified acellular pertussis components and bulk purified hepatitis B surface antigen onto a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate and admixture of a suitable quantity of PRP conjugate and suitable quantities of purified and inactivated, monovalent harvests of human polioviruses 1, 2 and 3 or a suitable quantity of a trivalent pool of such monovalent harvests. Suitable antimicrobial preservatives may be added.

Vaccine with the haemophilus component in a separate container. The final bulk of diphtheria, tetanus, pertussis, hepatitis B and poliovirus component is prepared by adsorption, separately or together, of suitable quantities of bulk purified diphtheria toxoid, bulk purified tetanus toxoid, bulk purified acellular pertussis components and bulk purified hepatitis B surface antigen onto a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate and admixture of suitable quantities of purified and inactivated, monovalent harvests of human polioviruses 1, 2 and 3 or a suitable pool of such monovalent harvests. This final bulk is filled separately. Suitable antimicrobial preservatives may be added. The final bulk of the haemophilus component is prepared by dilution of the bulk conjugate to the final concentration with a suitable diluent. A stabiliser may be added.

Only final bulks that comply with the following requirements may be used in the preparation of the final lot.

Bovine serum albumin. Determined on the poliomyelitis components by a suitable immunochemical method (2.7.1) after purification of the harvests and before preparation of the final bulk vaccine, before addition of the adsorbent, the amount of bovine serum albumin is such that the content in the final vaccine will be not more than 50 ng per single human dose.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

Where the haemophilus component is in a separate container, the final bulk of the haemophilus component is freeze-dried. Only a final lot that is satisfactory with respect to the test for osmolality shown below and with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided that the tests for osmolality, for absence of residual pertussis toxin and irreversibility of pertussis toxoid and for antimicrobial preservative and the diphtheria, tetanus and pertussis component assays have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the free formaldehyde content has been determined on the bulk purified antigens and the purified monovalent harvests or the trivalent pool of polioviruses or the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

Provided that the test for bovine serum albumin has been carried out with satisfactory results on the trivalent pool of inactivated monovalent harvests of polioviruses or on the final bulk vaccine, it may be omitted on the final lot.

If an *in vivo* assay is used for the hepatitis B component, provided it has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Provided the *in vivo* assay for the poliomyelitis component has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Free PRP. For vaccines with all components in the same container, the free PRP content is determined on the non-absorbed fraction. Unbound PRP is determined on the haemophilus component after removal of the conjugate, for example by anion-exchange, size-exclusion or hydrophobic chromatography, ultrafiltration or other validated methods. The amount of free PRP is not greater than that approved for the particular product.

Bacterial endotoxins (2.6.14): less than the limit approved for the particular product.

Osmolality (2.2.35). The osmolality of the vaccine, reconstituted where applicable, is within the limits approved for the particular preparation.

IDENTIFICATION

If the vaccine is presented with the haemophilus component in a separate vial: identification tests A, B, C, D and E are carried out using the vial containing the diphtheria, tetanus, pertussis, hepatitis B and poliomyelitis components; identification test F is carried out on the vial containing the haemophilus components.

- A. Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method is given as an example. Dissolve in the vaccine to be examined sufficient sodium citrate R to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.
- B. Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method is given as an example. The clear supernatant liquid obtained during identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.

- C. The clear supernatant liquid obtained during identification test A reacts with a specific antisera to the pertussis components of the vaccine when examined by suitable immunochemical methods (2.7.1).
- D. The hepatitis B component is identified by a suitable immunochemical method (2.7.1), for example the *in vitro* assay or by a suitable electrophoretic method (2.2.31).
- E. The vaccine is shown to contain human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1), such as determination of D-antigen by enzyme-linked immunosorbent assay (ELISA).
- F. The PRP and the haemophilus carrier protein are identified by a suitable immunochemical method (2.7.1).

TESTS

If the product is presented with the haemophilus component in a separate container: the tests for absence of residual pertussis toxin and irreversibility of pertussis toxoid, free formaldehyde, aluminium, antimicrobial preservative and sterility are carried out on the container with the diphtheria, tetanus, pertussis, poliomyelitis and hepatitis B components; the tests for PRP content, water, antimicrobial preservative, aluminium (where applicable) and sterility are carried out on the container with the haemophilus component.

Some tests for the haemophilus component are carried out on the freeze-dried product rather than on the bulk conjugate where the freeze-drying process may affect the component to be tested.

Absence of residual pertussis toxin and irreversibility of pertussis toxoid. This test is not necessary for the product obtained by genetic modification. Use 3 groups each of not fewer than 5 histamine-sensitive mice. Inject intraperitoneally into the first group twice the single human dose of the vaccine stored at 2-8 °C. Inject intraperitoneally into the second group twice the single human dose of the vaccine incubated at 37 °C for 4 weeks. Inject diluent into the third group of mice. After 5 days, inject into each mouse 2 mg of histamine base intraperitoneally in a volume not exceeding 0.5 ml and observe for 24 h. The test is invalid if 1 or more control mice die following histamine challenge. The vaccine complies with the test if no animal in the first or second group dies following histamine challenge. If 1 mouse dies in either or both of the first and second groups, the test may be repeated with the same number of mice or with a greater number and the results of valid tests combined; the vaccine complies with the test if, in both of the groups given the vaccine, not more than 5 per cent of the total number of mice die following histamine challenge.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject intravenously threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

PRP: minimum 80 per cent of the amount of PRP stated on the label, for a vaccine with the haemophilus component in a separate container.

For a vaccine with all components in the same container: the PRP content determined on the non-absorbed fraction is not less than that approved for the product.

PRP is determined either by assay of ribose (2.5.31) or phosphorus (2.5.18), by an immunochemical method (2.7.1) or by anion-exchange liquid chromatography (2.2.29) with pulsed-amperometric detection.

Aluminium (2.5.13): maximum 1.25 mg of aluminium (Al) per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l of free formaldehyde per single human dose.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Water (2.5.12): maximum 3.0 per cent for the freeze-dried haemophilus component.

Sterility (2.6.1). It complies with the test for sterility.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than the minimum potency stated on the label.

Unless otherwise justified and authorised, the minimum potency stated on the label is 30 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose.

Pertussis component. The vaccine complies with the assay of pertussis vaccine (acellular) (2.7.16).

Hepatitis B component. The vaccine complies with the assay of hepatitis B vaccine (2.7.15).

Poliomyelitis component

D-antigen content. As a measure of consistency of production, determine the D-antigen content for human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1) using a reference preparation calibrated in European Pharmacopoeia D-antigen units. For each type, the content, expressed with reference to the amount of D-antigen stated on the label, is within the limits approved for the particular product. *Poliomyelitis vaccine (inactivated) BRP* is calibrated in European Pharmacopoeia units and intended for use in the assay of D antigen. The European Pharmacopoeia unit and the International Unit are equivalent.

In vivo test. The vaccine complies with the *in vivo* assay of poliomyelitis vaccine (inactivated) (2.7.20).

LABELLING

The label states:

- the minimum number of International Units of diphtheria and tetanus toxoid per single human dose,
- the names and amounts of the pertussis components per single human dose,
- the amount of HBsAg per single human dose,
- the nominal amount of poliovirus of each type (1, 2 and 3), expressed in European Pharmacopoeia Units of D-antigen, per single human dose,
- the types of cells used for production of the poliomyelitis and the hepatitis B components,
- the number of micrograms of PRP per single human dose,

- the type and nominal amount of carrier protein per single human dose,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen,
- where applicable, that the vaccine contains a pertussis toxin-like protein produced by genetic modification.

01/2005:2065

DIPHTHERIA, TETANUS, PERTUSSIS (ACELLULAR, COMPONENT), POLIOMYELITIS (INACTIVATED) AND HAEMOPHILUS TYPE b CONJUGATE VACCINE (ADSORBED)

Vaccinum diphtheriae, tetani, pertussis
sine cellulis ex elementis praeparatum
poliomyelitis inactivatum et haemophili
stirpe b coniugatum adsorbatum

DEFINITION

Diphtheria, tetanus, pertussis (acellular, component), poliomyelitis (inactivated) and haemophilus type b conjugate vaccine (adsorbed) is a combined vaccine composed of: diphtheria formol toxoid; tetanus formol toxoid; individually purified antigenic components of *Bordetella pertussis*; suitable strains of human polioviruses 1, 2 and 3 grown in suitable cell cultures and inactivated by a suitable method; polyribosylribitol phosphate (PRP) covalently bound to a carrier protein; a mineral adsorbent such as aluminium hydroxide or hydrated aluminium phosphate. The product is presented with the haemophilus component in a separate container the contents of which are mixed with the other components immediately before use.

The formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani* respectively.

The vaccine contains either pertussis toxoid or a pertussis-toxin-like protein free from toxic properties produced by expression of a genetically modified form of the corresponding gene. Pertussis toxoid is prepared from pertussis toxin by a method that renders the toxin harmless while maintaining adequate immunogenic properties and avoiding reversion to toxin. The acellular pertussis component may also contain filamentous haemagglutinin, pertactin (a 69 kDa outer-membrane protein) and other defined components of *B. pertussis* such as fimbrial-2 and fimbrial-3 antigens. The latter 2 antigens may be co-purified. The antigenic composition and characteristics are based on evidence of protection and freedom from unexpected reactions in the target group for which the vaccine is intended.

PRP is a linear copolymer composed of repeated units of 3-β-D-ribofuranosyl-(1→1)-ribitol-5-phosphate [(C₁₀H₁₉O₁₂P)_n], with a defined molecular size and derived from a suitable strain of *Haemophilus influenzae* type b. The carrier protein, when conjugated to PRP, is capable of inducing a T-cell-dependent B-cell immune response to the polysaccharide.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

The content of bacterial endotoxins (2.6.14) in bulk purified diphtheria toxoid, tetanus toxoid, pertussis components, purified, inactivated monovalent poliovirus harvests and bulk PRP conjugate is determined to monitor the purification procedure and to limit the amount in the final vaccine. For each component, the content of bacterial endotoxins is less than the limit approved for the particular vaccine and, in any case, the contents are such that the final vaccine contains less than 100 IU per single human dose.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9), and with the following test for specific toxicity of the diphtheria and tetanus components: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 42 days of the injection any of the animals shows signs of or dies from diphtheria, toxæmia or tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

During development studies and wherever revalidation is necessary, it shall be demonstrated by tests in animals that the vaccine induces a T-cell dependent B-cell immune response to PRP.

As part of consistency studies the assays of the diphtheria, tetanus, pertussis and poliomyelitis components are carried out on a suitable number of batches of vaccine reconstituted as for use. For subsequent routine control, the assays of these components may be carried out without mixing with the haemophilus component.

Reference vaccine(s). Provided valid assays can be performed, monocomponent reference vaccines may be used for the assays on the combined vaccine. If this is not possible because of interaction between the components of the combined vaccine or because of the difference in composition between monocomponent reference vaccine and the test vaccine, a batch of combined vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine may be stabilised by a method that has been shown to have no effect on the assay procedure.

PRODUCTION OF THE COMPONENTS

The production of the components complies with the requirements of the monographs on *Diphtheria vaccine (adsorbed)* (0443), *Tetanus vaccine (adsorbed)* (0452), *Pertussis vaccine (acellular, component, adsorbed)* (1356), *Poliomyelitis vaccine (inactivated)* (0214) and *Haemophilus type b conjugate vaccine* (1219).

FINAL BULK

The final bulk of the diphtheria, tetanus, pertussis and poliomyelitis components is prepared by adsorption, separately or together, of suitable quantities of bulk purified diphtheria toxoid, bulk purified tetanus toxoid and bulk purified acellular pertussis components onto a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate and admixture of suitable quantities of purified,

monovalent harvests of human polioviruses 1, 2 and 3 or a suitable quantity of a trivalent pool of such monovalent harvests. Suitable antimicrobial preservatives may be added. The final bulk of the haemophilus component is prepared by dilution of the bulk conjugate to the final concentration with a suitable diluent. A stabiliser may be added.

Only final bulks that comply with the following requirements may be used in the preparation of the final lot.

Bovine serum albumin. Determined on the poliomyelitis components by a suitable immunochemical method (2.7.1) during preparation of the final bulk vaccine, before addition of the adsorbent, the amount of bovine serum albumin is such that the content in the final vaccine will be not more than 50 ng per single human dose.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk of the haemophilus component is freeze-dried.

Only a final lot that is satisfactory with respect to the test for osmolality shown below and with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided that the test for absence of residual pertussis toxin and irreversibility of pertussis toxoid, the test for antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided that the free formaldehyde content has been determined on the bulk purified antigens and the purified monovalent harvests or the trivalent pool of polioviruses or the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

Provided that the *in vivo* assay for the poliomyelitis component has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Osmolality (2.2.35). The osmolality of the vaccine, reconstituted where applicable, is within the limits approved for the particular preparation.

Free PRP. Unbound PRP is determined on the haemophilus component after removal of the conjugate, for example by anion-exchange, size-exclusion or hydrophobic chromatography, ultrafiltration or other validated methods. The amount of free PRP is not greater than that approved for the particular product.

IDENTIFICATION

Identification tests A, B, C and D are carried out using the vial containing the diphtheria, tetanus, pertussis and poliomyelitis components; identification test E is carried out on the vial containing the haemophilus component.

- A. Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.
- B. Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear

supernatant liquid obtained during identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.

- C. The pertussis components are identified by suitable immunochemical methods (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained during identification test A reacts with specific antisera to the pertussis components of the vaccine.
- D. The vaccine is shown to contain human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1), such as determination of D-antigen by enzyme-linked immunosorbent assay (ELISA).
- E. The haemophilus component is identified by a suitable immunochemical method (2.7.1) for PRP.

TESTS

The tests for absence of residual pertussis toxin, irreversibility of pertussis toxoid, aluminium, free formaldehyde, antimicrobial preservative and sterility are carried out on the container with the diphtheria, tetanus, pertussis and poliomyelitis components; the tests for PRP content, water, sterility and pyrogens are carried out on the container with the haemophilus component.

Some tests for the haemophilus component may be carried out on the freeze-dried product rather than on the bulk conjugate where the freeze-drying process may affect the component to be tested.

Absence of residual pertussis toxin and irreversibility of pertussis toxoid. *This test is not necessary for the product obtained by genetic modification.* Use 3 groups each of not fewer than 5 histamine-sensitive mice. Inject intraperitoneally into the first group twice the single human dose of the vaccine stored at 2–8 °C. Inject intraperitoneally into the second group twice the single human dose of the vaccine incubated at 37 °C for 4 weeks. Inject diluent into the third group of mice. After 5 days, inject into each mouse 2 mg of histamine base intraperitoneally in a volume not exceeding 0.5 ml and observe for 24 h. The test is invalid if 1 or more control mice die following histamine challenge. The vaccine complies with the test if no animal in the first or second group dies following histamine challenge. If 1 mouse dies in either or both of the first and second groups, the test may be repeated with the same number of mice or with a greater number and the results of valid tests combined; the vaccine complies with the test if, in both of the groups given the vaccine, not more than 5 per cent of the total number of mice die following histamine challenge.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject intravenously threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

PRP: minimum 80 per cent of the amount of PRP stated on the label. PRP is determined either by assay of ribose (2.5.31) or phosphorus (2.5.18), by an immunochemical method (2.7.1) or by anion-exchange liquid chromatography (2.2.29) with pulsed-ampereometric detection.

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Water (2.5.12): maximum 3.0 per cent for the haemophilus component.

Sterility (2.6.1). It complies with the test for sterility.

Pyrogens (2.6.8). It complies with the test for pyrogens. Inject per kilogram of the rabbit's mass a quantity of the vaccine equivalent to: 1 µg of PRP for a vaccine with diphtheria toxoid or CRM 197 diphtheria protein as carrier; 0.1 µg of PRP for a vaccine with tetanus toxoid as carrier; 0.025 µg of PRP for a vaccine with OMP as a carrier.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

Unless otherwise justified and authorised, the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 30 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8). The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose.

Pertussis component. It complies with the assay of pertussis vaccine (acellular) (2.7.16).

Poliomyelitis component

D-antigen content. As a measure of consistency of production, determine the D-antigen content for human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1) using a reference preparation calibrated in Ph. Eur. Units of D-antigen. For each type, the content, expressed with reference to the amount of D-antigen stated on the label, is within the limits approved for the particular product. *Poliomyelitis vaccine (inactivated) BRP* is calibrated in Ph. Eur. Units and intended for use in the assay of D-antigen. The Ph. Eur. Unit and the IU are equivalent.

In vivo test. The vaccine complies with the *in vivo* assay of poliomyelitis vaccine (inactivated) (2.7.20).

LABELLING

The label states:

- the minimum number of International Units of diphtheria and tetanus toxoid per single human dose,
- the names and amounts of the pertussis components per single human dose,
- the nominal amount of poliovirus of each type (1, 2 and 3), expressed in European Pharmacopoeia Units of D-antigen, per single human dose,
- the type of cells used for production of the poliomyelitis component,
- the number of micrograms of PRP per single human dose,
- the type and nominal amount of carrier protein per single human dose,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen,
- where applicable, that the vaccine contains a pertussis toxin-like protein produced by genetic modification.

01/2005:2061

DIPHtheria, TETANUS, PERTUSSIS AND POLIOMYELITIS (INACTIVATED) VACCINE (ADSORBED)

Vaccinum diphtheriae, tetani, pertussis et poliomyelitis inactivatum adsorbatum

DEFINITION

Diphtheria, tetanus, pertussis and poliomyelitis (inactivated) vaccine (adsorbed) is a combined vaccine containing: diphtheria formol toxoid; tetanus formol toxoid; an inactivated suspension of *Bordetella pertussis*; suitable strains of human polioviruses 1, 2 and 3 grown in suitable cell cultures and inactivated by a validated method; a mineral adsorbent such as aluminium hydroxide or hydrated aluminium phosphate.

The formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani* respectively.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

Reference vaccine(s). Provided valid assays can be performed, monocomponent reference vaccines may be used for the assays on the combined vaccine. If this is not possible because of interaction between the components of the combined vaccine or because of the difference in composition between monocomponent reference vaccine and the test vaccine, a batch of combined vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine may be stabilised by a method that has been shown to have no effect on the assay procedure.

Specific toxicity of the diphtheria and tetanus components.

The production method is validated to demonstrate that the product, if tested, would comply with the following test: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 42 days of the injection any of the animals shows signs of or dies from diphtheria toxæmia or tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

PRODUCTION OF THE COMPONENTS

The production of the components complies with the requirements of the monographs on *Diphtheria vaccine (adsorbed)* (0443), *Tetanus vaccine (adsorbed)* (0452), *Pertussis vaccine (adsorbed)* (0161) and *Poliomyelitis vaccine (inactivated)* (0214).

FINAL BULK VACCINE

The final bulk vaccine is prepared by adsorption onto a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate, separately or together, of suitable quantities of bulk purified diphtheria toxoid and bulk purified tetanus toxoid and admixture of suitable quantities of an inactivated suspension of *B. pertussis* and purified monovalent harvests of human polioviruses 1, 2 and 3

or a suitable quantity of a trivalent pool of such purified monovalent harvests. Suitable antimicrobial preservatives may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Bovine serum albumin. Determined on the poliomyelitis components by a suitable immunochemical method (2.7.1) during preparation of the final bulk vaccine, before addition of the adsorbent, the amount of bovine serum albumin is such that the content in the final vaccine will be not more than 50 ng per single human dose.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to the test for osmolality and with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided that the tests for specific toxicity of the pertussis component and antimicrobial preservative, and the assays for the diphtheria, tetanus and pertussis components have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided that the free formaldehyde content has been determined on the bulk purified antigens, the inactivated *B. pertussis* suspension and the purified monovalent harvests or the trivalent pool of polioviruses or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

Provided that the *in vivo* assay for the poliomyelitis component has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Osmolality (2.2.35). The osmolality of the vaccine is within the limits approved for the particular preparation.

IDENTIFICATION

- Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.
- Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained during identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.
- The centrifugation residue obtained in identification A may be used. Other suitable methods for separating the bacteria from the adsorbent may also be used. Identify pertussis vaccine by agglutination of the bacteria from the resuspended precipitate by antisera specific to *B. pertussis* or by the assay of the pertussis component prescribed under Assay.
- The vaccine is shown to contain human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1) such as the determination of D-antigen by enzyme-linked immunosorbent assay (ELISA).

TESTS

Specific toxicity of the pertussis component. Use not fewer than 5 healthy mice each weighing 14–16 g for the vaccine group and for the saline control. Use mice of the same sex or distribute males and females equally between the groups. Allow the animals access to food and water for at least 2 h before injection and during the test. Inject each mouse of the vaccine group intraperitoneally with 0.5 ml, containing a quantity of the vaccine equivalent to not less than half the single human dose. Inject each mouse of the control group with 0.5 ml of a 9 g/l sterile solution of *sodium chloride R*, preferably containing the same amount of antimicrobial preservative as that injected with the vaccine. Weigh the groups of mice immediately before the injection and 72 h and 7 days after the injection. The vaccine complies with the test if: (a) at the end of 72 h the total mass of the group of vaccinated mice is not less than that preceding the injection; (b) at the end of 7 days the average increase in mass per vaccinated mouse is not less than 60 per cent of that per control mouse; and (c) not more than 5 per cent of the vaccinated mice die during the test. The test may be repeated and the results of the tests combined.

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). It complies with the test for sterility.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 30 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8).

If the test is carried out in guinea pigs, the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose; if the test is carried out in mice, the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 60 IU per single human dose.

Pertussis component. Carry out the assay of pertussis vaccine (2.7.7).

The estimated potency is not less than 4 IU per single human dose and the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 2 IU per single human dose.

Poliomyelitis component

D-antigen content. As a measure of consistency of production, determine the D-antigen content for human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1) using a reference preparation calibrated in European Pharmacopoeia Units of D-antigen. For each type, the content, expressed with reference to the amount of D-antigen stated on the label, is within the limits approved for the particular product. *Poliomyelitis vaccine (inactivated) BRP* is calibrated in European Pharmacopoeia Units and intended for use in the assay of D-antigen. The European Pharmacopoeia Unit and the International Unit are equivalent.

In vivo test. The vaccine complies with the *in vivo* assay of poliomyelitis vaccine (inactivated) (2.7.20).

LABELLING

The label states:

- the minimum number of International Units of diphtheria and tetanus toxoid per single human dose,
- the minimum number of International Units of pertussis vaccine per single human dose,
- the nominal amount of poliovirus of each type (1, 2 and 3), expressed in European Pharmacopoeia Units of D-antigen, per single human dose,
- the type of cells used for production of the poliomyelitis component,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:2066

DIPHTHERIA, TETANUS, PERTUSSIS, POLIOMYELITIS (INACTIVATED) AND HAEMOPHILUS TYPE b CONJUGATE VACCINE (ADSORBED)

Vaccinum diphtheriae, tetani, pertussis, poliomyelitis inactivatum et haemophili stirpe b coniugatum adsorbatum

DEFINITION

Diphtheria, tetanus, pertussis, poliomyelitis (inactivated) and haemophilus type b conjugate vaccine (adsorbed) is a combined vaccine composed of: diphtheria formol toxoid; tetanus formol toxoid; an inactivated suspension of *Bordetella pertussis*; suitable strains of human polioviruses 1, 2 and 3 grown in suitable cell cultures and inactivated by a suitable method; polyribosylribitol phosphate (PRP) covalently bound to a carrier protein; a mineral adsorbent such as aluminium hydroxide or hydrated aluminium phosphate. The product is presented with the haemophilus component in a separate container, the contents of which are mixed with the other components immediately before use.

The formol toxoids are prepared from the toxins produced by the growth of *Corynebacterium diphtheriae* and *Clostridium tetani* respectively.

PRP is a linear copolymer composed of repeated units of 3-β-D-ribofuranosyl-(1→1)-ribitol-5-phosphate [(C₁₀H₁₉O₁₂P)_n], with a defined molecular size and derived from a suitable strain of *Haemophilus influenzae* type b. The carrier protein, when conjugated to PRP, is capable of inducing a T-cell-dependent B-cell immune response to the polysaccharide.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

During development studies and wherever revalidation is necessary, it shall be demonstrated by tests in animals that the vaccine induces a T-cell dependent B-cell immune response to PRP.

As part of consistency studies the assays of the diphtheria, tetanus, pertussis and poliomyelitis components are carried out on a suitable number of batches of vaccine reconstituted as for use. For subsequent routine control, the assays of these components may be carried out without mixing with the haemophilus component.

Reference vaccine(s). Provided valid assays can be performed, monocomponent reference vaccines may be used for the assays on the combined vaccine. If this is not possible because of interaction between the components of the combined vaccine or because of the difference in composition between monocomponent reference vaccine and the test vaccine, a batch of combined vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine may be stabilised by a method that has been shown to have no effect on the assay procedure.

Specific toxicity of the diphtheria and tetanus components. The production method is validated to demonstrate that the product, if tested, would comply with the following test: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 42 days of the injection any of the animals shows signs of or dies from diphtheria toxæmia or tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

PRODUCTION OF THE COMPONENTS

The production of the components complies with the requirements of the monographs on *Diphtheria vaccine (adsorbed)* (0443), *Tetanus vaccine (adsorbed)* (0452), *Pertussis vaccine (adsorbed)* (0161), *Poliomyelitis vaccine (inactivated)* (0214) and *Haemophilus type b conjugate vaccine* (1219).

FINAL BULKS

The final bulk of the diphtheria, tetanus, pertussis and poliomyelitis components is prepared by adsorption, separately or together, of suitable quantities of bulk purified diphtheria toxoid, and bulk purified tetanus toxoid onto a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate and admixture of suitable quantities of an inactivated suspension of *B. pertussis* and of purified, monovalent harvests of human polioviruses 1, 2 and 3 or a suitable quantity of a trivalent pool of such monovalent harvests. Suitable antimicrobial preservatives may be added.

The final bulk of the haemophilus component is prepared by dilution of the bulk conjugate to the final concentration with a suitable diluent. A stabiliser may be added.

Only final bulks that comply with the following requirements may be used in the preparation of the final lot.

Bovine serum albumin. Determined on the poliomyelitis components by a suitable immunochemical method (2.7.1) during preparation of the final bulk vaccine, before addition of the adsorbent, the amount of bovine serum albumin is such that the content in the final vaccine will be not more than 50 ng per single human dose.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk of the haemophilus component is freeze-dried.

Only a final lot that is satisfactory with respect to the test for osmolality shown below and with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided that the tests for specific toxicity of the pertussis component and antimicrobial preservative, and the assays for the diphtheria, tetanus and pertussis components have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided that the free formaldehyde content has been determined on the bulk purified antigens, the inactivated *B. pertussis* suspension and the purified monovalent harvests or the trivalent pool of polioviruses or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

Provided that the *in vivo* assay for the poliomyelitis component has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Osmolality (2.2.35). The osmolality of the vaccine, reconstituted where applicable, is within the limits approved for the particular preparation.

Free PRP. Unbound PRP is determined on the haemophilus component after removal of the conjugate, for example by anion-exchange, size-exclusion or hydrophobic chromatography, ultrafiltration or other validated methods. The amount of free PRP is not greater than that approved for the particular product.

IDENTIFICATION

Identification tests A, B, C and D are carried out using the vial containing the diphtheria, tetanus, pertussis and poliomyelitis components; identification test E is carried out on the vial containing the haemophilus component.

- Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.
- Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. The clear supernatant liquid obtained during identification test A reacts with a suitable tetanus antitoxin, giving a precipitate.
- The centrifugation residue obtained in identification A may be used. Other suitable methods for separating the bacteria from the adsorbent may also be used. Identify pertussis vaccine by agglutination of the bacteria from the resuspended precipitate by antisera specific to *B. pertussis* or by the assay of the pertussis component prescribed under Assay.

D. The vaccine is shown to contain human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1), such as determination of D-antigen by enzyme-linked immunosorbent assay (ELISA).

E. The haemophilus component is identified by a suitable immunochemical method (2.7.1) for PRP.

TESTS

The tests for specific toxicity of the pertussis component, aluminium, free formaldehyde, antimicrobial preservative and sterility are carried out on the container with diphtheria, tetanus, pertussis and poliomyelitis components; the tests for PRP, water, sterility and pyrogens are carried out on the container with the haemophilus component.

Some tests for the haemophilus component may be carried out on the freeze-dried product rather than on the bulk conjugate where the freeze-drying process may affect the component to be tested.

Specific toxicity of the pertussis component. Use not fewer than 5 healthy mice each weighing 14–16 g, for the vaccine group and for the saline control. Use mice of the same sex or distribute males and females equally between the groups. Allow the animals access to food and water for at least 2 h before injection and during the test. Inject each mouse of the vaccine group intraperitoneally with 0.5 ml, containing a quantity of the vaccine equivalent to not less than half the single human dose. Inject each mouse of the control group with 0.5 ml of a 9 g/l sterile solution of *sodium chloride R*, preferably containing the same amount of antimicrobial preservative as that injected with the vaccine. Weigh the groups of mice immediately before the injection and 72 h and 7 days after the injection. The vaccine complies with the test if: (a) at the end of 72 h the total mass of the group of vaccinated mice is not less than that preceding the injection; (b) at the end of 7 days the average increase in mass per vaccinated mouse is not less than 60 per cent of that per control mouse; and (c) not more than 5 per cent of the vaccinated mice die during the test. The test may be repeated and the results of the tests combined.

PRP: minimum 80 per cent of the amount of PRP stated on the label. PRP is determined either by assay of ribose (2.5.31) or phosphorus (2.5.18), by an immunochemical method (2.7.1) or by anion-exchange liquid chromatography (2.2.29) with pulsed-amprometric detection.

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Water (2.5.12): maximum 3.0 per cent for the haemophilus component.

Sterility (2.6.1). It complies with the test for sterility.

Pyrogens (2.6.8). It complies with the test for pyrogens. Inject per kilogram of the rabbit's mass a quantity of the vaccine equivalent to: 1 µg of PRP for a vaccine with

diphtheria toxoid or CRM 197 diphtheria protein as carrier; 0.1 µg of PRP for a vaccine with tetanus toxoid as carrier; 0.025 µg of PRP for a vaccine with OMP as carrier.

ASSAY

Diphtheria component. Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 30 IU per single human dose.

Tetanus component. Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8).

If the test is carried out in guinea-pigs, the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose; if the test is carried out in mice, the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 60 IU per single human dose.

Pertussis component. Carry out the assay of pertussis vaccine (2.7.7).

The estimated potency is not less than 4 IU per single human dose and the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 2 IU per single human dose.

Poliomyelitis component

D-antigen content. As a measure of consistency of production, determine the D-antigen content for human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1) using a reference preparation calibrated in European Pharmacopoeia Units of D-antigen. For each type, the content, expressed with reference to the amount of D-antigen stated on the label, is within the limits approved for the particular product. *Poliomyelitis vaccine (inactivated) BRP* is calibrated in European Pharmacopoeia Units and intended for use in the assay of D-antigen. The European Pharmacopoeia Unit and the International Unit are equivalent.

In vivo test. The vaccine complies with the *in vivo* assay of poliomyelitis vaccine (inactivated) (2.7.20).

LABELLING

The label states:

- the minimum number of International Units of diphtheria and tetanus toxoid per single human dose,
- the minimum number of International Units of pertussis vaccine per single human dose,
- the nominal amount of poliovirus of each type (1, 2 and 3), expressed in European Pharmacopoeia Units of D-antigen, per single human dose,
- the type of cells used for production of the poliomyelitis component,
- the number of micrograms of PRP per single human dose,
- the type and nominal amount of carrier protein per single human dose,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:0443

DIPHTHERIA VACCINE (ADSORBED)**Vaccinum diphtheriae adsorbatum****DEFINITION**

Diphtheria vaccine (adsorbed) is a preparation of diphtheria formol toxoid with a mineral adsorbent. The formol toxoid is prepared from the toxin produced by the growth of *Corynebacterium diphtheriae*.

PRODUCTION**GENERAL PROVISIONS**

Specific toxicity. The production method is validated to demonstrate that the product, if tested, would comply with the following test: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 42 days of the injection any of the animals shows signs of or dies from diphtheria toxæmia, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

BULK PURIFIED TOXOID

For the production of diphtheria toxin, from which toxoid is prepared, seed cultures are managed in a defined seed-lot system in which toxinogenicity is conserved and, where necessary, restored by deliberate reselection. A highly toxinogenic strain of *Corynebacterium diphtheriae* with known origin and history is grown in a suitable liquid medium. At the end of cultivation, the purity of each culture is tested and contaminated cultures are discarded. Toxin-containing culture medium is separated aseptically from the bacterial mass as soon as possible. The toxin content (Lf per millilitre) is checked to monitor consistency of production. Single harvests may be pooled to prepare the bulk purified toxoid. The toxin is purified to remove components likely to cause adverse reactions in humans. The purified toxin is detoxified with formaldehyde by a method that avoids destruction of the immunogenic potency of the toxoid and reversion of the toxoid to toxin, particularly on exposure to heat. Alternatively, purification may be carried out after detoxification.

Only bulk purified toxoid that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

Absence of toxin and irreversibility of toxoid. Using the same buffer solution as for the final vaccine, without adsorbent, prepare a solution of bulk purified toxoid at 100 Lf/ml. Divide the solution into 2 equal parts. Maintain 1 part at 5 ± 3 °C and the other at 37 °C for 6 weeks. Carry out a test in Vero cells for active diphtheria toxin using 50 µl/well of both samples. The sample should not contain antimicrobial preservatives and detoxifying agents should be determined to be below the concentration toxic to Vero cells. Non-specific toxicity may be eliminated by dialysis.

Use freshly trypsinised Vero cells at a suitable concentration, for example 2.5×10^5 ml⁻¹ and a reference diphtheria toxin diluted in 100 Lf/ml diphtheria toxoid. A suitable reference diphtheria toxin will contain either not less than 100 LD₅₀/ml or 67 to 133 lr/100 in 1 Lf and 25 000 to

50 000 minimal reacting doses for guinea-pig skin in 1 Lf (*diphtheria toxin BRP* is suitable for use as the reference toxin). Dilute the toxin in 100 Lf/ml diphtheria toxoid to a suitable concentration, for example 2×10^{-4} Lf/ml. Prepare serial twofold dilutions of the diluted diphtheria toxin and use undiluted test samples (50 µl/well). Distribute them in the wells of a sterile tissue culture plate containing a medium suitable for Vero cells. To ascertain that any cytotoxic effect noted is specific to diphtheria toxin, prepare in parallel dilutions where the toxin is neutralised by a suitable concentration of diphtheria antitoxin, for example 100 IU/ml. Include control wells without toxoid or toxin and with non-toxic toxoid at 100 Lf/ml on each plate to verify normal cell growth. Add cell suspension to each well, seal the plates and incubate at 37 °C for 5-6 days. Cytotoxic effect is judged to be present where there is complete metabolic inhibition of the Vero cells, indicated by the pH indicator of the medium. Confirm cytopathic effect by microscopic examination or suitable staining such as MTT dye. The test is invalid if 5×10^{-5} Lf/ml of reference diphtheria toxin in 100 Lf/ml toxoid has no cytotoxic effect on Vero cells or if the cytotoxic effect of this amount of toxin is not neutralised in the wells containing diphtheria antitoxin. The bulk purified toxoid complies with the test if no toxicity neutralisable by antitoxin is found in either sample.

Antigenic purity. Not less than 1500 Lf per milligram of protein nitrogen.

FINAL BULK VACCINE

The final bulk vaccine is prepared by adsorption of a suitable quantity of bulk purified toxoid onto a mineral carrier such as hydrated aluminium phosphate or aluminium hydroxide; the resulting mixture is approximately isotonic with blood. Suitable antimicrobial preservatives may be added. Certain antimicrobial preservatives, particularly those of the phenolic type, adversely affect the antigenic activity and must not be used.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the test for antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the free formaldehyde content has been determined on the bulk purified antigens or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

IDENTIFICATION

Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge

until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.

TESTS

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

ASSAY

Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 30 IU per single human dose.

LABELLING

The label states:

- the minimum number of International Units per single human dose,
- where applicable, that the vaccine is intended for primary vaccination of children and is not necessarily suitable for reinforcing doses or for administration to adults,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:0646

DIPHTHERIA VACCINE (ADSORBED) FOR ADULTS AND ADOLESCENTS

Vaccinum diphtheriae adulti et adolescentis adsorbatum

DEFINITION

Diphtheria vaccine (adsorbed) for adults and adolescents is a preparation of diphtheria formol toxoid with a mineral adsorbent. The formol toxoid is prepared from the toxin produced by the growth of *Corynebacterium diphtheriae*. It shall have been demonstrated to the competent authority that the quantity of diphtheria toxoid used does not produce adverse reactions in subjects from the age groups for which the vaccine is intended.

PRODUCTION

GENERAL PROVISIONS

Specific toxicity. The production method is validated to demonstrate that the product, if tested, would comply with the following test: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 42 days of the injection any of the animals shows signs of or dies from diphtheria toxæmia, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

BULK PURIFIED TOXOID

The bulk purified toxoid is prepared as described in the monograph on *Diphtheria vaccine (adsorbed)* (0443) and complies with the requirements prescribed therein.

FINAL BULK VACCINE

The final bulk vaccine is prepared by adsorption of a suitable quantity of bulk purified toxoid onto a mineral carrier such as hydrated aluminium phosphate or aluminium hydroxide; the resulting mixture is approximately isotonic with blood. Suitable antimicrobial preservatives may be added. Certain antimicrobial preservatives, particularly those of the phenolic type, adversely affect the antigenic activity and must not be used.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the test for antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the free formaldehyde content has been determined on the bulk purified toxoid or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

IDENTIFICATION

Diphtheria toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate. If a satisfactory result is not obtained with a vaccine adsorbed on aluminium hydroxide, carry out the test as follows. Centrifuge 15 ml of the vaccine to be examined and suspend the residue in 5 ml of a freshly prepared mixture of 1 volume of a 56 g/l solution of *sodium edetate R* and 49 volumes of a 90 g/l solution of *disodium hydrogen phosphate R*. Maintain at 37 °C for not less than 6 h and centrifuge. The clear supernatant liquid reacts with a suitable diphtheria antitoxin, giving a precipitate.

TESTS

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

ASSAY

Carry out one of the prescribed methods for the assay of diphtheria vaccine (adsorbed) (2.7.6).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 2 IU per single human dose.

LABELLING

The label states:

- the minimum number of International Units per single human dose,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:1219

HAEMOPHILUS TYPE b CONJUGATE VACCINE

Vaccinum haemophili stirpe b coniugatum

DEFINITION

Haemophilus type b conjugate vaccine is a liquid or freeze-dried preparation of a polysaccharide, derived from a suitable strain of *Haemophilus influenzae* type b, covalently bound to a carrier protein. The polysaccharide, polyribosylribitol phosphate, referred to as PRP, is a linear copolymer composed of repeated units of 3-β-D-ribofuranosyl-(1→1)-ribitol-5-phosphate $[(C_{10}H_{19}O_{12}P)_n]$, with a defined molecular size. The carrier protein, when conjugated to PRP, is capable of inducing a T-cell-dependent B-cell immune response to the polysaccharide.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently haemophilus type b conjugate vaccines of adequate safety and immunogenicity in man. The production of PRP and of the carrier are based on seed-lot systems.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

During development studies and wherever revalidation of the manufacturing process is necessary, it shall be demonstrated by tests in animals that the vaccine consistently induces a T-cell-dependent B-cell immune response.

The stability of the final lot and relevant intermediates is evaluated using one or more indicator tests. Such tests may include determination of molecular size, determination of free PRP in the conjugate and the immunogenicity test in mice. Taking account of the results of the stability testing, release requirements are set for these indicator tests to ensure that the vaccine will be satisfactory at the end of the period of validity.

BACTERIAL SEED LOTS

The seed lots of *H. influenzae* type b are shown to be free from contamination by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

No complex products of animal origin are included in the menstruum used for preservation of strain viability, either for freeze-drying or for frozen storage.

It is recommended that PRP produced by the seed lot be characterised using nuclear magnetic resonance spectrometry (2.2.33).

H. INFLUENZAE TYPE b POLYSACCHARIDE (PRP)

H. influenzae type b is grown in a liquid medium that does not contain high-molecular-mass polysaccharides; if any ingredient of the medium contains blood-group substances, the process shall be validated to demonstrate that after the purification step they are no longer detectable. The bacterial purity of the culture is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera. The culture may be inactivated. PRP is separated from the culture medium and purified by a suitable method. Volatile matter, including water, in the purified polysaccharide is determined by a suitable method such as thermogravimetry (2.2.34); the result is used to calculate the results of certain tests with reference to the dried substance, as prescribed below.

Only PRP that complies with the following requirements may be used in the preparation of the conjugate.

Identification. PRP is identified by an immunochemical method (2.7.1) or other suitable method, for example ^1H nuclear magnetic resonance spectrometry (2.2.33).

Molecular-size distribution. The percentage of PRP eluted before a given K_0 value or within a range of K_0 values is determined by size-exclusion chromatography (2.2.30); an acceptable value is established for the particular product and each batch of PRP must be shown to comply with this limit. Limits for currently approved products, using the indicated stationary phases, are shown for information in Table 1219-1. Where applicable, the molecular-size distribution is also determined after chemical modification of the polysaccharide.

Liquid chromatography (2.2.29) with multiple-angle laser light-scattering detection may also be used for determination of molecular-size distribution.

A validated determination of the degree of polymerisation or of the weight-average molecular weight and the dispersion of molecular masses may be used instead of the determination of molecular size distribution.

Ribose (2.5.31). Not less than 32 per cent, calculated with reference to the dried substance.

Phosphorus (2.5.18): 6.8 per cent to 9.0 per cent, calculated with reference to the dried substance.

Protein (2.5.16). Not more than 1.0 per cent, calculated with reference to the dried substance. Use sufficient PRP to allow detection of proteins at concentrations of 1 per cent or greater.

Nucleic acid (2.5.17). Not more than 1.0 per cent, calculated with reference to the dried substance.

Bacterial endotoxins (2.6.14): less than 25 IU per microgram of PRP.

Residual reagents. Where applicable, tests are carried out to determine residues of reagents used during inactivation and purification. An acceptable value for each reagent is established for the particular product and each batch of PRP must be shown to comply with this limit. Where validation studies have demonstrated removal of a residual reagent, the test on PRP may be omitted.

Table 1219-1. – Product characteristics and specifications for PRP and carrier protein in currently approved products

Carrier			Haemophilus polysaccharide		Conjugation	
Type	Purity	Nominal amount per dose	Type of PRP	Nominal amount per dose	Coupling method	Procedure
Diphtheria toxoid	> 1500 Lf per milligram of nitrogen	18 µg	Size-reduced PRP K_0 : 0.6-0.7, using cross-linked agarose for chromatography R	25 µg	cyanogen bromide activation of PRP	activated diphtheria toxoid (D-AH ⁺), cyanogen bromide-activated PRP
Tetanus toxoid	> 1500 Lf per milligram of nitrogen	20 µg	PRP ≥ 50 % $\leq K_0$: 0.30, using cross-linked agarose for chromatography R	10 µg	carbodi-imide mediated	ADH-activated PRP (PRP-cov.-AH) + tetanus toxoid + EDAC
CRM 197 diphtheria protein	> 90 % of diphtheria protein	25 µg	Size-reduced PRP Dp = 15-35 or 10-35	10 µg	reductive amination (1-step method) or <i>N</i> -hydroxysuccinimide activation	direct coupling of PRP to CRM 197 (cyanoborohydride activated)
Meningococcal group B outer membrane protein (OMP)	outer membrane protein vesicles: ≤ 8 % of lipopolysaccharide	125 µg or 250 µg	Size-reduced PRP $K_0 < 0.6$, using cross-linked agarose for chromatography R or $M_w > 50 \times 10^3$	7.5 µg or 15 µg	thioether bond	PRP activation by CDI PRP-IM + BuA2 + BrAc = PRP-BuA2-BrAc + thioactivated OMP
ADH = adipic acid dihydrazide BrAc = bromoacetyl chloride BuA2 = butane-1,4-diamide CDI = carbonyldiimidazole			Dp = degree of polymerisation EDAC = 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide IM = imidazolium M_w = weight-average molecular weight			

CARRIER PROTEIN

The carrier protein is chosen so that when the PRP is conjugated it is able to induce a T-cell-dependent B-cell immune response. Currently approved carrier proteins and coupling methods are listed for information in Table 1219-1. The carrier proteins are produced by culture of suitable micro-organisms; the bacterial purity of the culture is verified; the culture may be inactivated; the carrier protein is purified by a suitable method.

Only a carrier protein that complies with the following requirements may be used in the preparation of the conjugate.

Identification. The carrier protein is identified by a suitable immunochemical method (2.7.1).

Sterility (2.6.1). Carry out the test using for each medium 10 ml or the equivalent of one-hundred doses, whichever is less.

Diphtheria toxoid. Diphtheria toxoid is produced as described in *Diphtheria vaccine (adsorbed) (0443)* and complies with the requirements prescribed therein for bulk purified toxoid.

Tetanus toxoid. Tetanus toxoid is produced as described in *Tetanus vaccine (adsorbed) (0452)* and complies with the requirements prescribed therein for bulk purified toxoid, except that the antigenic purity is not less than 1500 Lf per milligram of protein nitrogen.

Diphtheria protein CRM 197. It contains not less than 90 per cent of diphtheria CRM 197 protein, determined by a suitable method. Suitable tests are carried out, for validation or routinely, to demonstrate that the product is nontoxic.

OMP (meningococcal group B Outer Membrane Protein complex). OMP complies with the following requirements for lipopolysaccharide and pyrogens.

Lipopolysaccharide. Not more than 8 per cent of lipopolysaccharide, determined by a suitable method.

Pyrogens (2.6.8). Inject into each rabbit 0.25 µg of OMP per kilogram of body mass.

BULK CONJUGATE

PRP is chemically modified to enable conjugation; it is usually partly depolymerised either before or during this procedure. Reactive functional groups or spacers may be introduced into the carrier protein or PRP prior to conjugation. As a measure of consistency, the extent of derivatisation is monitored. The conjugate is obtained by the covalent binding of PRP and carrier protein. Where applicable, unreacted but potentially reactogenic functional groups are made unreactive by means of capping agents; the conjugate is purified to remove reagents.

Only a bulk conjugate that complies with the following requirements may be used in the preparation of the final bulk vaccine. For each test and for each particular product, limits of acceptance are established and each batch of conjugate must be shown to comply with these limits. Limits applied to currently approved products for some of these tests are listed for information in Table 1219-2. For a freeze-dried vaccine, some of the tests may be carried out on the final lot rather than on the bulk conjugate where the freeze-drying process may affect the component being tested.

PRP. The PRP content is determined by assay of phosphorus (2.5.18) or by assay of ribose (2.5.31) or by an immunochemical method (2.7.1).

Protein. The protein content is determined by a suitable chemical method (for example, 2.5.16).

PRP to protein ratio. Determine the ratio by calculation.

Molecular-size distribution. Molecular-size distribution is determined by size-exclusion chromatography (2.2.30).

Free PRP. Unbound PRP is determined after removal of the conjugate, for example by anion-exchange, size-exclusion or hydrophobic chromatography, ultrafiltration or other validated methods.

Free carrier protein. Determine the content by a suitable method, either directly or by deriving the content by calculation from the results of other tests. The amount is within the limits approved for the particular product.

Table 1219.2. – Bulk conjugate requirements for currently approved products

Test	Protein carrier			
	Diphtheria toxoid	Tetanus toxoid	CRM 197	OMP
Free PRP	< 37 %	< 20 %	< 25 %	< 15 %
Free protein	< 4 %	< 1 %, where applicable	< 1 % or < 2 %, depending on the coupling method	not applicable
PRP to protein ratio	1.25 - 1.8	0.30 - 0.55	0.3 - 0.7	0.05 - 0.1
Molecular size (K_0):				
<i>cross-linked agarose for chromatography R</i>	95 % < 0.75	60 % < 0.2	50 % 0.3 - 0.6	85 % < 0.3
<i>cross-linked agarose for chromatography R1</i>	0.6-0.7	85 % < 0.5		

Unreacted functional groups. No unreacted functional groups are detectable in the bulk conjugate unless process validation has shown that unreacted functional groups detectable at this stage are removed during the subsequent manufacturing process (for example, owing to short half-life).

Residual reagents. Removal of residual reagents such as cyanide, EDAC (ethyl dimethylaminopropyl carbodi-imide) and phenol is confirmed by suitable tests or by validation of the process.

Sterility (2.6.1). Carry out the test using for each medium 10 ml or the equivalent of 100 doses, whichever is less.

FINAL BULK VACCINE

An adjuvant, an antimicrobial preservative and a stabiliser may be added to the bulk conjugate before dilution to the final concentration with a suitable diluent.

Only a final bulk vaccine that complies with the following requirements may be used in preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The content is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). It complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification and Tests may be released for use. Provided the test for antimicrobial preservative has been carried out on the final bulk vaccine, it may be omitted on the final lot.

pH (2.2.3). The pH of the vaccine, reconstituted if necessary, is within the range approved for the particular product.

Free PRP. Unbound PRP is determined after removal of the conjugate, for example by anion-exchange, size-exclusion or hydrophobic chromatography, ultrafiltration or other validated methods. The amount of free PRP is not greater than that approved for the particular product.

IDENTIFICATION

The vaccine is identified by a suitable immunochemical method (2.7.1) for PRP.

TESTS

PRP. Not less than 80 per cent of the amount of PRP stated on the label. PRP is determined either by assay of ribose (2.5.31) or phosphorus (2.5.18), by an immunochemical method (2.7.1) or by anion-exchange liquid chromatography with pulsed amperometric detection (2.2.29).

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The content is not less than the minimum amount shown to be effective and not greater than 115 per cent of the quantity stated on the label.

Water (2.5.12): maximum 3.0 per cent for freeze-dried vaccines.

Sterility (2.6.1). It complies with the test for sterility.

Pyrogens (2.6.8). It complies with the test for pyrogens. Inject per kilogram of the rabbit's mass a quantity of the vaccine equivalent to: 1 µg of PRP for a vaccine with diphtheria toxoid or CRM 197 diphtheria protein as carrier; 0.1 µg of PRP for a vaccine with tetanus toxoid as carrier; 0.025 µg of PRP for a vaccine with OMP as carrier.

LABELLING

The label states:

- the number of micrograms of PRP per human dose,
- the type and nominal amount of carrier protein per single human dose.

01/2005:1526

HEPATITIS A (INACTIVATED) AND HEPATITIS B (rDNA) VACCINE (ADSORBED)

Vaccinum hepatitis A inactivatum et hepatitis B (ADNr) adsorbatum

DEFINITION

Hepatitis A (inactivated) and hepatitis B (rDNA) vaccine (adsorbed) is a suspension consisting of a suitable strain of hepatitis A virus, grown in cell cultures and inactivated by a validated method, and of hepatitis B surface antigen (HBsAg), a component protein of hepatitis B virus obtained by recombinant DNA technology; the antigens are adsorbed on a mineral carrier, such as aluminium hydroxide or hydrated aluminium phosphate.

PRODUCTION

GENERAL PROVISIONS

The two components are prepared as described in the monographs on *Hepatitis A vaccine (inactivated, adsorbed) (1107)* and *Hepatitis B vaccine (rDNA) (1056)* and comply with the requirements prescribed therein.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

Reference preparation. The reference preparation is part of a representative batch shown to be at least as immunogenic in animals as a batch that, in clinical studies in young healthy

adults, produced not less than 95 per cent seroconversion, corresponding to a level of neutralising antibody recognised to be protective, after a full-course primary immunisation. For hepatitis A, an antibody level not less than 20 mIU/ml determined by enzyme-linked immunosorbent assay is recognised as being protective. For hepatitis B, an antibody level not less than 10 mIU/ml against HBsAg is recognised as being protective.

FINAL BULK VACCINE

The final bulk vaccine is prepared from one or more inactivated harvests of hepatitis A virus and one or more batches of purified antigen.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the tests for free formaldehyde (where applicable) and antimicrobial preservative content (where applicable) have been carried out on the final bulk vaccine with satisfactory results, they may be omitted on the final lot. If the assay of the hepatitis A and/or the hepatitis B component is carried out *in vivo*, then provided it has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

IDENTIFICATION

The vaccine is shown to contain hepatitis A virus antigen and hepatitis B surface antigen by suitable immunochemical methods (2.7.1), using specific antibodies or by the mouse immunogenicity tests described under Assay.

TESTS

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than the minimum amount shown to be effective and is not greater than 115 per cent of that stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

Bacterial endotoxins (2.6.14): less than 2 IU per human dose.

ASSAY

Hepatitis A component. The vaccine complies with the assay of hepatitis A vaccine (2.7.14).

Hepatitis B component. The vaccine complies with the assay of hepatitis B vaccine (rDNA) (2.7.15).

LABELLING

The label states:

- the amount of hepatitis A virus antigen and hepatitis B surface antigen per container,
- the type of cells used for production of the vaccine,

- the name and amount of the adsorbent used,
- that the vaccine must be shaken before use,
- that the vaccine must not be frozen.

01/2005:1107

HEPATITIS A VACCINE (INACTIVATED, ADSORBED)

Vaccinum hepatitis A inactivatum adsorbatum

DEFINITION

Hepatitis A vaccine (inactivated, adsorbed) is a suspension consisting of a suitable strain of hepatitis A virus grown in cell cultures, inactivated by a validated method and adsorbed on a mineral carrier.

PRODUCTION

Production of the vaccine is based on a virus seed-lot system and a cell-bank system. The production method shall have been shown to yield consistently vaccines that comply with the requirements for immunogenicity, safety and stability.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

Unless otherwise justified and authorised, the virus in the final vaccine shall not have undergone more passages from the master seed lot than were used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy.

Reference preparation. A part of a batch shown to be at least as immunogenic in animals as a batch that, in clinical studies in young healthy adults, produced not less than 95 per cent seroconversion, corresponding to a level of neutralising antibody accepted to be protective, after a full-course primary immunisation is used as a reference preparation. An antibody level of 20 mIU/ml determined by enzyme-linked immunosorbent assay is recognised as being protective.

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in a human diploid cell line (5.2.3) or in a continuous cell line approved by the competent authority.

SEED LOTS

The strain of hepatitis A virus used to prepare the master seed lot shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation.

Only a seed lot that complies with the following requirements may be used for virus propagation.

Identification. Each master and working seed lot is identified as hepatitis A virus using specific antibodies.

Virus concentration. The virus concentration of each master and working seed lot is determined to monitor consistency of production.

Extraneous agents. The master and working seed lots comply with the requirements for seed lots for virus vaccines (2.6.16). In addition, if primary monkey cells have been used for isolation of the strain, measures are taken to ensure that the strain is not contaminated with simian viruses such as simian immunodeficiency virus and filoviruses.

VIRUS PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are being handled. Animal serum (but not human

serum) may be used in the cell culture media. Serum and trypsin used in the preparation of cell suspensions and media are shown to be free from extraneous agents. The cell culture media may contain a pH indicator, such as phenol red, and antibiotics at the lowest effective concentration. Not less than 500 ml of the cell cultures employed for vaccine production is set aside as uninfected cell cultures (control cells). Multiple harvests from the same production cell culture may be pooled and considered as a single harvest.

Only a single harvest that complies with the following requirements may be used in the preparation of the vaccine. When the determination of the ratio of virus concentration to antigen content has been carried out on a suitable number of single harvests to demonstrate production consistency, it may subsequently be omitted as a routine test.

Identification. The test for antigen content also serves to identify the single harvest.

Bacterial and fungal contamination (2.6.1). The single harvest complies with the test for sterility, carried out using 10 ml for each medium.

Mycoplasmas (2.6.7). The single harvest complies with the test for mycoplasmas, carried out using 1 ml for each medium.

Control cells. The control cells of the production cell culture comply with a test for identification and the requirements for extraneous agents (2.6.16).

Antigen content. Determine the hepatitis A antigen content by a suitable immunochemical method (2.7.1) to monitor production consistency; the content is within the limits approved for the particular product.

Ratio of virus concentration to antigen content. The consistency of the ratio of the concentration of infectious virus, determined by a suitable cell culture method, to antigen content is established by validation on a suitable number of single harvests.

PURIFICATION AND PURIFIED HARVEST

The harvest, which may be a pool of several single harvests, is purified by validated methods. If continuous cell lines are used for production, the purification process shall have been shown to reduce consistently the level of host-cell DNA.

Only a purified harvest that complies with the following requirements may be used in the preparation of the inactivated harvest.

Virus concentration. The concentration of infectious virus in the purified harvest is determined by a suitable cell culture method to monitor production consistency and as a starting point for monitoring the inactivation curve.

Antigen:total protein ratio. Determine the hepatitis A virus antigen content by a suitable immunochemical method (2.7.1). Determine the total protein by a validated method. The ratio of hepatitis A virus antigen content to total protein content is within the limits approved for the particular product.

Bovine serum albumin. Not more than 50 ng in the equivalent of a single human dose, determined by a suitable immunochemical method (2.7.1). Where appropriate in view of the manufacturing process, other suitable protein markers may be used to demonstrate effective purification.

Residual host-cell DNA. If a continuous cell line is used for virus propagation, the content of residual host-cell DNA, determined using a suitable method, is not greater than 100 pg in the equivalent of a single human dose.

Residual chemicals. If chemical substances are used during the purification process, tests for these substances are carried out on the purified harvest (or on the inactivated

harvest), unless validation of the process has demonstrated total clearance. The concentration must not exceed the limits approved for the particular product.

INACTIVATION AND INACTIVATED HARVEST

Several purified harvests may be pooled before inactivation. In order to avoid interference with the inactivation process, virus aggregation must be prevented or aggregates must be removed immediately before and/or during the inactivation process. The virus suspension is inactivated by a validated method; the method shall have been shown to be consistently capable of inactivating hepatitis A virus without destroying the antigenic and immunogenic activity; for each inactivation procedure, an inactivation curve is plotted representing residual live virus concentration measured at not fewer than three points in time (for example, on days 0, 1 and 2 of the inactivation process). If formaldehyde is used for inactivation, the presence of excess free formaldehyde is verified at the end of the inactivation process.

Only an inactivated harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Inactivation. Carry out an amplification test for residual infectious hepatitis A virus by inoculating a quantity of the inactivated harvest equivalent to 5 per cent of the batch or, if the harvest contains the equivalent of 30 000 doses or more, not less than 1500 doses of vaccine into cell cultures of the same type as those used for production of the vaccine; incubate for a total of not less than 70 days making not fewer than one passage of cells within that period. At the end of the incubation period, carry out a test of suitable sensitivity for residual infectious virus. No evidence of hepatitis A virus multiplication is found in the samples taken at the end of the inactivation process. Use infectious virus inocula concurrently as positive controls to demonstrate cellular susceptibility and absence of interference. Incubate for a total of not less than 70 days, making not fewer than one passage of cells within that period.

Sterility (2.6.1). The inactivated viral harvest complies with the test for sterility, carried out using 10 ml for each medium.

Bacterial endotoxins (2.6.14): less than 2 IU in the equivalent of a single human dose.

Antigen content. Determine the hepatitis A virus antigen content by a suitable immunochemical method (2.7.1).

Residual chemicals. See under Purification and purified harvest.

FINAL BULK VACCINE

The final bulk vaccine is prepared from one or more inactivated harvests. Approved adjuvants, stabilisers and antimicrobial preservatives may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Sterility (2.6.1). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile containers. The containers are then closed so as to avoid contamination.

Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the tests for free formaldehyde

(where applicable) and antimicrobial preservative content (where applicable) have been carried out on the final bulk vaccine with satisfactory results, these tests may be omitted on the final lot. If the assay is carried out using mice or other animals, then provided it has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

IDENTIFICATION

The vaccine is shown to contain hepatitis A virus antigen by a suitable immunochemical method (2.7.1) using specific antibodies or by the *in vivo* assay (2.7.14).

TESTS

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than the minimum amount shown to be effective and is not greater than 115 per cent of that stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

ASSAY

The vaccine complies with the assay of hepatitis A vaccine (2.7.14).

LABELLING

The label states the biological origin of the cells used for the preparation of the vaccine.

01/2005:1935

HEPATITIS A VACCINE (INACTIVATED, VIROSOME)

Vaccinum hepatitis A inactivatum virosomale

DEFINITION

Hepatitis A vaccine (inactivated, virosome) is a suspension of a suitable strain of hepatitis A virus grown in cell cultures and inactivated by a validated method. Virosomes composed of influenza proteins of a strain approved for the particular product and phospholipids are used as adjuvants.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

Reference preparation. A reference preparation of inactivated hepatitis A antigen is calibrated against a batch of hepatitis A vaccine (inactivated, virosome) that, in clinical studies in young healthy adults, produced not less than 95 per cent seroconversion, corresponding to a level of neutralising antibody accepted to be protective, after a full-course primary immunisation. An antibody level not less than 20 mIU/ml determined by enzyme-linked immunosorbent assay is recognised as being protective.

PREPARATION OF HEPATITIS A ANTIGEN

Production of the hepatitis A antigen is based on a virus seed-lot system and a cell-bank system. The production method shall have been shown to yield consistently vaccines that comply with the requirements for immunogenicity, safety and stability.

Unless otherwise justified and authorised, the virus in the final vaccine shall not have undergone more passages from the master seed lot than were used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy.

SUBSTRATE FOR PROPAGATION OF HEPATITIS A VIRUS

The virus is propagated in a human diploid cell line (5.2.3).

SEED LOTS OF HEPATITIS A VIRUS

The strain of hepatitis A virus used to prepare the master seed lot shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation.

Only a seed lot that complies with the following requirements may be used for virus propagation.

Identification. Each master and working seed lot is identified as hepatitis A virus using specific antibodies.

Virus concentration. The virus concentration of each master and working seed lot is determined to monitor consistency of production.

Extraneous agents. The master and working seed lots comply with the requirements for seed lots for virus vaccines (2.6.16).

PROPAGATION AND HARVEST OF HEPATITIS A VIRUS

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Animal serum (but not human serum) may be used in the cell culture media. Serum and trypsin used in the preparation of cell suspensions and media are shown to be free from extraneous agents. The cell culture media may contain a pH indicator such as phenol red and antibiotics at the lowest effective concentration. Not less than 500 ml of the cell cultures employed for vaccine production is set aside as uninfected cell cultures (control cells). Multiple harvests from the same production cell culture may be pooled and considered as a single harvest.

Only a single harvest that complies with the following requirements may be used in the preparation of the vaccine. When the determination of the ratio of virus concentration to antigen content has been carried out on a suitable number of single harvests to demonstrate consistency, it may subsequently be omitted as a routine test.

Identification. The test for antigen content also serves to identify the single harvest.

Bacterial and fungal contamination (2.6.1). The single harvest complies with the test for sterility, carried out using 10 ml for each medium.

Mycoplasmas (2.6.7). The single harvest complies with the test for mycoplasmas.

Control cells. The control cells of the production cell culture comply with a test for identity and the requirements for extraneous agents (2.6.16).

Antigen content. Determine the hepatitis A antigen content by a suitable immunochemical method (2.7.1) to monitor production consistency; the content is within the limits approved for the particular product.

Ratio of virus concentration to antigen content. The consistency of the ratio of the concentration of infectious virus, as determined by a suitable cell culture method, to antigen content is established by validation on a suitable number of single harvests.

PURIFICATION AND PURIFIED HARVEST OF HEPATITIS A VIRUS

The harvest, which may be a pool of several single harvests, is purified by validated methods. If continuous cell lines are used for production, the purification process shall have been shown to reduce consistently the level of host-cell DNA.

Only a purified harvest that complies with the following requirements may be used in the preparation of the inactivated harvest.

Virus concentration. The concentration of infective virus in the purified harvest is determined by a suitable cell culture method to monitor production consistency and as a starting point for monitoring the inactivation curve.

Ratio of antigen to total protein. Determine the hepatitis A virus antigen content by a suitable immunochemical method (2.7.1). Determine the total protein by a validated method. The ratio of hepatitis A virus antigen content to total protein content is within the limits approved for the particular product.

Bovine serum albumin: maximum 50 ng per single human dose if foetal bovine serum is used, determined by a suitable immunochemical method (2.7.1). Where appropriate in view of the manufacturing process, other suitable protein markers may be used to demonstrate effective purification.

Residual chemicals. If chemical substances are used during the purification process, tests for these substances are carried out on the purified harvest (or on the inactivated harvest), unless validation of the process has demonstrated total clearance. The concentration must not exceed the limits approved for the particular product.

INACTIVATION AND INACTIVATED HARVEST OF HEPATITIS A VIRUS

Several purified harvests may be pooled before inactivation. In order to avoid interference with the inactivation process, virus aggregation must be prevented or aggregates must be removed immediately before and/or during the inactivation process. The virus suspension is inactivated by a validated method; the method shall have been shown to be consistently capable of inactivating hepatitis A virus without destroying the antigenic and immunogenic activity; for each inactivation procedure, an inactivation curve is plotted representing residual live virus concentration measured on at least 3 occasions (for example, on days 0, 1 and 2 of the inactivation process). If formaldehyde is used for inactivation, the presence of excess free formaldehyde is verified at the end of the inactivation process.

Only an inactivated harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Inactivation. Carry out an amplification test for residual infectious hepatitis A virus by inoculating a quantity of the inactivated harvest equivalent to 5 per cent of the batch or, if the harvest contains the equivalent of 30 000 doses or more, not less than 1500 doses of vaccine into cell cultures of the same type as those used for production of the vaccine; incubate for a total of not less than 70 days making not fewer than 1 passage of cells within that period. At the end of the incubation period, carry out a test of suitable sensitivity for residual infectious virus. No evidence of hepatitis A virus multiplication is found in the samples taken at the end of the

inactivation process. Use infective virus inocula concurrently as positive controls to demonstrate cellular susceptibility and absence of interference.

Sterility (2.6.1). The inactivated viral harvest complies with the test for sterility, carried out using 10 ml for each medium.

Bacterial endotoxins (2.6.14): less than 2 IU of endotoxin in the equivalent of a single human dose.

Antigen content. Determine the hepatitis A virus antigen content by a suitable immunochemical method (2.7.1).

Residual chemicals. See under Purification and purified harvest.

PREPARATION OF INACTIVATED INFLUENZA VIRUS

The production of influenza viruses is based on a seed-lot system. Working seed lots represent not more than 15 passages from the approved reassorted virus or the approved virus isolate. The final production represents 1 passage from the working seed lot. The strain of influenza virus to be used is approved by the competent authority.

SUBSTRATE FOR PROPAGATION OF INFLUENZA VIRUS

Influenza virus seed to be used in the production of vaccine is propagated in fertilised eggs from chicken flocks free from specified pathogens (5.2.2) or in suitable cell cultures (5.2.4), such as chick-embryo fibroblasts or chick kidney cells obtained from chicken flocks free from specified pathogens (5.2.2). For production, the virus is grown in the allantoic cavity of fertilised hens' eggs from healthy flocks.

SEED LOTS OF INFLUENZA VIRUS

The haemagglutinin and neuraminidase antigens of each seed lot are identified as originating from the correct strain of influenza virus by suitable methods.

Only a working virus seed lot that complies with the following requirements may be used in the preparation of the monovalent pooled harvest.

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml for each medium.

Mycoplasmas (2.6.7). Carry out the test for mycoplasmas, using 10 ml.

PROPAGATION AND HARVEST OF INFLUENZA VIRUS

An antimicrobial agent may be added to the inoculum. After incubation at a controlled temperature, the allantoic fluids are harvested and combined to form the monovalent pooled harvest. An antimicrobial agent may be added at the time of harvest. At no stage in the production is penicillin or streptomycin used.

POOLED HARVEST OF INFLUENZA VIRUS

To limit the possibility of contamination, inactivation is initiated as soon as possible after preparation. The virus is inactivated by a method that has been demonstrated on 3 consecutive batches to be consistently effective for the manufacturer. The inactivation process shall have been shown to be capable of inactivating the influenza virus without destroying antigenicity of haemagglutinin. The inactivation process shall also have been shown to be capable of inactivating avian leucosis viruses and mycoplasmas. If the monovalent pooled harvest is stored after inactivation, it is held at a temperature of 5 ± 3 °C. If formaldehyde solution is used, the concentration does not exceed 0.2 g/l of CH₂O at any time during inactivation; if betapropiolactone is used, the concentration does not exceed 0.1 per cent V/V at any time during inactivation.

Only a pooled harvest that complies with the following requirements may be used in the preparation of the virosomes.

Haemagglutinin antigen. Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it. Carry out the test at 20–25 °C.

Sterility (2.6.1). Carry out the test for sterility, using 10 ml for each medium.

Viral inactivation. Inoculate 0.2 ml of the harvest into the allantoic cavity of each of 10 fertilised eggs and incubate at 33–37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest 0.5 ml of the allantoic fluid from each surviving embryo and pool the fluids. Inoculate 0.2 ml of the pooled fluid into a further 10 fertilised eggs and incubate at 33–37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest about 0.1 ml of the allantoic fluid from each surviving embryo and examine each individual harvest by a haemagglutination test. If haemagglutination is found for any of the fluids, carry out for that fluid a further passage in eggs and test for haemagglutination; no haemagglutination occurs.

Ovalbumin: maximum 1 µg of ovalbumin in the equivalent of 1 human dose, determined by a suitable technique using a suitable reference preparation of ovalbumin.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Residual chemicals. Tests are carried out on the monovalent pooled harvest for the chemicals used for inactivation, the limits being approved by the competent authority.

PREPARATION OF VIROSOMES

Inactivated influenza virions are solubilised using a suitable detergent and are purified by high-speed centrifugation in order to obtain supernatants containing mainly influenza antigens. After the addition of suitable phospholipids, virosomes are formed by removal of the detergent either by adsorption chromatography or another suitable technique

Only virosomes that comply with the following requirements may be used in the preparation of the final bulk vaccine.

Haemagglutinin content. Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it.

Phospholipids. The content and identity of the phospholipids are determined by suitable immunochemical or physico-chemical methods.

Ratio of phospholipid to haemagglutinin. The ratio of phospholipid content to haemagglutinin content is within the limits approved for the particular product.

Residual chemicals. Tests are carried out for the chemicals used during the process. The concentration of each residual chemical is within the limits approved for the particular product.

FINAL BULK VACCINE

The bulk vaccine is prepared by adding virosomes to inactivated hepatitis A viruses to yield an approved hepatitis A antigen:haemagglutinin ratio. Several bulks may be pooled, and approved stabilisers and antimicrobial preservatives may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Protein content. The amount of protein is determined using a suitable technique, the limits being approved by the competent authority.

Phospholipids. The content and identity of the phospholipids are determined by suitable immunochemical or physico-chemical methods. The amount of phospholipids complies with the limits approved for the particular product.

Haemagglutinin content. Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1). The amount of haemagglutinin must not exceed the limits approved for the particular product.

Hepatitis A antigen content. Determine the hepatitis A antigen content by a suitable immunochemical method. The amount of antigen must not exceed the limits approved for the particular product.

Ratio of hepatitis A antigen to haemagglutinin. The ratio of hepatitis A antigen content to haemagglutinin content is within the limits approved for the particular product.

Ovalbumin: maximum 1 µg of ovalbumin per human dose, determined by a suitable technique using a suitable reference preparation of ovalbumin.

Virosome size. The size distribution of the virosome-hepatitis A virus mixture is within the limits approved for the particular product.

Sterility (2.6.1). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Residual chemicals. If chemical substances are used during the formulation process, tests for these substances are carried out, the limits being approved by the competent authority.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile containers. The containers are then closed so as to avoid contamination.

Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the tests for free formaldehyde (where applicable) and antimicrobial preservative content (where applicable) have been carried out on the final bulk vaccine with satisfactory results, these tests may be omitted on the final lot. If the assay is carried out *in vivo*, provided it has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

IDENTIFICATION

The vaccine is shown to contain hepatitis A virus antigen by a suitable immunochemical method (2.7.1) using specific antibodies.

TESTS

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than the minimum amount shown to be effective and is not greater than 115 per cent of that stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

Bacterial endotoxins (2.6.14): less than 2 IU of endotoxin per human dose.

ASSAY

Determine the antigen content of the vaccine using a suitable immunochemical method (2.7.1) by comparison with the reference preparation. The acceptance criteria are approved for a given reference preparation by the competent authority.

LABELLING

The label states:

- the biological origin of the cells used for the preparation of the vaccine,
- that the carrier contains influenza proteins prepared in eggs,
- that the vaccine is not to be frozen,
- that the vaccine is to be shaken before use.

01/2005:1056

HEPATITIS B VACCINE (rDNA)

Vaccinum hepatitis B (ADNr)

DEFINITION

Hepatitis B vaccine (rDNA) is a preparation of hepatitis B surface antigen (HBsAg), a component protein of hepatitis B virus; the antigen may be adsorbed on a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate. The antigen is obtained by recombinant DNA technology.

PRODUCTION

GENERAL PROVISIONS

The vaccine shall have been shown to induce specific, protective antibodies in man. The production method shall have been shown to yield consistently vaccines that comply with the requirements for immunogenicity and safety.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

Hepatitis B vaccine (rDNA) is produced by the expression of the viral gene coding for HBsAg in yeast (*Saccharomyces cerevisiae*) or mammalian cells (Chinese hamster ovary (CHO) cells or other suitable cell lines), purification of the resulting HBsAg and the rendering of this antigen into an immunogenic preparation. The suitability and safety of the cells are approved by the competent authority.

The vaccine may contain the product of the S gene (major protein), a combination of the S gene and pre-S2 gene products (middle protein) or a combination of the S gene, the pre-S2 gene and pre-S1 gene products (large protein).

Reference preparation. The reference preparation is part of a representative batch shown to be at least as immunogenic in animals as a batch that, in clinical studies in young, healthy adults, produced not less than 95 per cent seroconversion, corresponding to a level of HBsAg neutralising antibody recognised to be protective, after a full-course primary immunisation. An antibody level not less than 10 mIU/ml is recognised as being protective.

CHARACTERISATION OF THE SUBSTANCE

Development studies are carried out to characterise the antigen. The complete protein, lipid and carbohydrate structure of the antigen is established. The morphological characteristics of the antigen particles are established by electron microscopy. The mean buoyant density of the antigen particles is determined by a physico-chemical

method, such as gradient centrifugation. The antigenic epitopes are characterised. The protein fraction of the antigen is characterised in terms of the primary structure (for example, by determination of the amino-acid composition, by partial amino-acid sequence analysis and by peptide mapping).

CULTURE AND HARVEST

Identity, microbial purity, plasmid retention and consistency of yield are determined at suitable production stages. If mammalian cells are used, tests for extraneous agents and mycoplasmas are performed in accordance with *Tests for extraneous agents in viral vaccines for human use (2.6.16)*, but using 200 ml of harvest in the test in cell culture for other extraneous agents.

PURIFIED ANTIGEN

Only a purified antigen that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Total protein. The total protein is determined by a validated method. The content is within the limits approved for the specific product.

Antigen content and identification. The quantity and specificity of HBsAg is determined in comparison with the International Standard for HBsAg subtype *ad* or an in-house reference, by a suitable immunochemical method (2.7.1) such as radio-immunoassay (RIA), enzyme-linked immunosorbent assay (ELISA), immunoblot (preferably using a monoclonal antibody directed against a protective epitope) or single radial diffusion. The antigen/protein ratio is within the limits approved for the specific product.

The molecular weight of the major band revealed following sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE) performed under reducing conditions corresponds to the value expected from the known nucleic acid and polypeptide sequences and possible glycosylation.

Antigenic purity. The purity of the antigen is determined by comparison with a reference preparation using liquid chromatography or other suitable methods such as SDS-PAGE with staining by acid blue 92 and silver. A suitable method is sensitive enough to detect a potential contaminant at a concentration of 1 per cent of total protein. Not less than 95 per cent of the total protein consists of hepatitis B surface antigen.

Composition. The content of proteins, lipids, nucleic acids and carbohydrates is determined.

Host-cell- and vector-derived DNA. If mammalian cells are used for production, not more than 10 pg of DNA in the quantity of purified antigen equivalent to a single human dose of vaccine.

Caesium. If a caesium salt is used during production, a test for residual caesium is carried out on the purified antigen. The content is within the limits approved for the specific product.

Sterility (2.6.1). The purified antigen complies with the test for sterility, carried out using 10 ml for each medium.

Additional tests on the purified antigen may be required depending on the production method used: for example, a test for residual animal serum where mammalian cells are used for production or tests for residual chemicals used during extraction and purification.

FINAL BULK VACCINE

An antimicrobial preservative and an adjuvant may be included in the vaccine.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the tests for free formaldehyde (where applicable) and antimicrobial preservative content (where applicable) have been carried out on the final bulk vaccine with satisfactory results, they may be omitted on the final lot. If the assay is carried out *in vivo*, then provided it has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

IDENTIFICATION

The assay or, where applicable, the electrophoretic profile, serves also to identify the vaccine.

TESTS

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than the minimum amount shown to be effective and is not greater than 115 per cent of that stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

Pyrogens (2.6.8). The vaccine complies with the test for pyrogens. Inject the equivalent of one human dose into each rabbit.

ASSAY

The vaccine complies with the assay of hepatitis B vaccine (rDNA) (2.7.15).

LABELLING

The label states:

- the amount of HBsAg per container,
- the type of cells used for production of the vaccine,
- the name and amount of the adsorbent used,
- that the vaccine must be shaken before use,
- that the vaccine must not be frozen.

01/2005:0158

INFLUENZA VACCINE (SPLIT VIRION, INACTIVATED)

Vaccinum influenzae inactivatum
ex virorum fragmentis praeparatum

DEFINITION

Influenza vaccine (split virion, inactivated) is a sterile, aqueous suspension of a strain or strains of influenza virus, type A or B, or a mixture of strains of the two types grown individually in fertilised hens' eggs, inactivated and treated so that the integrity of the virus particles has been disrupted without diminishing the antigenic properties of

the haemagglutinin and neuraminidase antigens. The stated amount of haemagglutinin antigen for each strain present in the vaccine is 15 µg per dose, unless clinical evidence supports the use of a different amount.

The vaccine is a slightly opalescent liquid.

PRODUCTION

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

CHOICE OF VACCINE STRAIN

The World Health Organisation reviews the world epidemiological situation annually and if necessary recommends new strains corresponding to prevailing epidemiological evidence.

Such strains are used in accordance with the regulations in force in the signatory states of the Convention on the Elaboration of a European Pharmacopoeia. It is now common practice to use reassorted strains giving high yields of the appropriate surface antigens. The origin and passage history of virus strains shall be approved by the competent authority.

SUBSTRATE FOR VIRUS PROPAGATION

Influenza virus seed to be used in the production of vaccine is propagated in fertilised eggs from chicken flocks free from specified pathogens (5.2.2) or in suitable cell cultures (5.2.4), such as chick-embryo fibroblasts or chick kidney cells obtained from chicken flocks free from specified pathogens (5.2.2). For production, the virus of each strain is grown in the allantoic cavity of fertilised hens' eggs from healthy flocks.

VIRUS SEED LOT

The production of vaccine is based on a seed-lot system. Working seed lots represent not more than 15 passages from the approved reassorted virus or the approved virus isolate. The final vaccine represents 1 passage from the working seed lot. The haemagglutinin and neuraminidase antigens of each seed lot are identified as originating from the correct strain of influenza virus by suitable methods.

Only a working virus seed lot that complies with the following requirements may be used in the preparation of the monovalent pooled harvest.

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml for each medium.

Mycoplasmas (2.6.7). Carry out the test for mycoplasmas, using 10 ml.

VIRUS PROPAGATION AND HARVEST

An antimicrobial agent may be added to the inoculum. After incubation at a controlled temperature, the allantoic fluids are harvested and combined to form a monovalent pooled harvest. An antimicrobial agent may be added at the time of harvest. At no stage in the production is penicillin or streptomycin used.

MONOVALENT POOLED HARVEST

To limit the possibility of contamination, inactivation is initiated as soon as possible after preparation. The virus is inactivated by a method that has been demonstrated on three consecutive batches to be consistently effective for the manufacturer. The inactivation process shall have been shown to be capable of inactivating the influenza virus without destroying its antigenicity; the process should cause minimum alteration of the haemagglutinin and neuraminidase antigens. The inactivation process shall also have been shown to be capable of inactivating avian leucosis viruses and mycoplasmas. If the monovalent pooled harvest is stored after inactivation, it is held at a

temperature of 5 ± 3 °C. If formaldehyde solution is used, the concentration does not exceed 0.2 g/l of CH₂O at any time during inactivation; if betapropiolactone is used, the concentration does not exceed 0.1 per cent V/V at any time during inactivation.

Before or after the inactivation procedure, the monovalent pooled harvest is concentrated and purified by high-speed centrifugation or other suitable method and the virus particles are disrupted into component subunits by the use of approved procedures. For each new strain, a validation test is carried out to show that the monovalent bulk consists predominantly of disrupted virus particles.

Only a monovalent pooled harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Haemagglutinin antigen. Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it⁽¹⁾. Carry out the test at 20 °C to 25 °C.

For some vaccines, the physical form of the haemagglutinin particles prevents quantitative determination by immunodiffusion after inactivation of the virus. For these vaccines, a determination of haemagglutinin antigen is made on the monovalent pooled harvest before inactivation. The production process is validated to demonstrate suitable conservation of haemagglutinin antigen and a suitable tracer is used for formulation, for example, protein content.

Neuraminidase antigen. The presence and type of neuraminidase antigen are confirmed by suitable enzymatic or immunological methods on the first 3 monovalent pooled harvests from each working seed lot.

Sterility (2.6.1). Carry out the test for sterility, using 10 ml for each medium.

Viral inactivation. Carry out the test described below under Tests.

Chemicals used for disruption. Tests are carried out on the monovalent pooled harvest for the chemicals used for disruption, the limits being approved by the competent authority.

FINAL BULK VACCINE

Appropriate quantities of the monovalent pooled harvests are blended to make the final bulk vaccine.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility, using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Tests and Assay may be released for use. Provided that the test for viral inactivation has been performed with satisfactory results on each monovalent pooled harvest and that the tests for

free formaldehyde, ovalbumin and total protein have been performed with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

IDENTIFICATION

The assay serves to confirm the antigenic specificity of the vaccine.

TESTS

Viral inactivation. Inoculate 0.2 ml of the vaccine into the allantoic cavity of each of 10 fertilised eggs and incubate at 33 °C to 37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest 0.5 ml of the allantoic fluid from each surviving embryo and pool the fluids. Inoculate 0.2 ml of the pooled fluid into a further 10 fertilised eggs and incubate at 33 °C to 37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest about 0.1 ml of the allantoic fluid from each surviving embryo and examine each individual harvest for live virus by a haemagglutination test. If haemagglutination is found for any of the fluids, carry out for that fluid a further passage in eggs and test for haemagglutination; no haemagglutination occurs.

Total protein. Not more than 6 times the total haemagglutinin content of the vaccine as determined in the assay, but in any case, not more than 100 µg of protein per virus strain per human dose and not more than a total of 300 µg of protein per human dose.

Ovalbumin. Not more than 1 µg of ovalbumin per human dose, determined by a suitable technique using a suitable reference preparation of ovalbumin.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). It complies with the test for sterility.

Bacterial endotoxins (2.6.14): less than 100 IU per human dose.

ASSAY

Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it⁽¹⁾. Carry out the test at 20 °C to 25 °C. The confidence limits ($P = 0.95$) are not less than 80 per cent and not more than 125 per cent of the estimated haemagglutinin antigen content. The lower confidence limit ($P = 0.95$) is not less than 80 per cent of the amount stated on the label for each strain.

For some vaccines, quantitative determination of haemagglutinin antigen with respect to available reference preparations is not possible. An immunological identification of the haemagglutinin antigen and a semi-quantitative determination are carried out instead by suitable methods.

LABELLING

The label states:

- that the vaccine has been prepared on eggs,
- the strain or strains of influenza virus used to prepare the vaccine,
- the method of inactivation,

(1) Reference haemagglutinin antigens are available from the National Institute for Biological Standards and Control, Blanche Lane, South Mimms, Potters Bar, Hertfordshire EN6 3QG, Great Britain.

- the haemagglutinin content in micrograms per virus strain per dose,
- the season during which the vaccine is intended to protect.

01/2005:0869

INFLUENZA VACCINE (SURFACE ANTIGEN, INACTIVATED)

Vaccinum influenzae inactivatum ex corticis antigeniis praeparatum

DEFINITION

Influenza vaccine (surface antigen, inactivated) is a sterile suspension of a strain or strains of influenza virus, type A or B, or a mixture of strains of the 2 types grown individually in fertilised hens' eggs, inactivated and treated so that the preparation consists predominantly of haemagglutinin and neuraminidase antigens, without diminishing the antigenic properties of these antigens. The stated amount of haemagglutinin antigen for each strain present in the vaccine is 15 µg per dose, unless clinical evidence supports the use of a different amount. The vaccine may contain an adjuvant.

PRODUCTION

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

CHOICE OF VACCINE STRAIN

The World Health Organisation reviews the world epidemiological situation annually and if necessary recommends new strains corresponding to prevailing epidemiological evidence.

Such strains are used in accordance with the regulations in force in the signatory states of the Convention on the Elaboration of a European Pharmacopoeia. It is now common practice to use reassorted strains giving high yields of the appropriate surface antigens. The origin and passage history of virus strains shall be approved by the competent authority.

SUBSTRATE FOR VIRUS PROPAGATION

Influenza virus seed to be used in the production of vaccine is propagated in fertilised eggs from chicken flocks free from specified pathogens (SPF) (5.2.2) or in suitable cell cultures (5.2.4), such as chick-embryo fibroblasts or chick kidney cells obtained from SPF chicken flocks (5.2.2). For production, the virus of each strain is grown in the allantoic cavity of fertilised hens' eggs from healthy flocks.

VIRUS SEED LOT

The production of vaccine is based on a seed-lot system. Working seed lots represent not more than 15 passages from the approved reassorted virus or the approved virus isolate. The final vaccine represents one passage from the working seed lot. The haemagglutinin and neuraminidase antigens of each seed lot are identified as originating from the correct strain of influenza virus by suitable methods.

Only a working virus seed lot that complies with the following requirements may be used in the preparation of the monovalent pooled harvest.

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml for each medium.

Mycoplasmas (2.6.7). Carry out the test for mycoplasmas, using 10 ml.

VIRUS PROPAGATION AND HARVEST

An antimicrobial agent may be added to the inoculum. After incubation at a controlled temperature, the allantoic fluids are harvested and combined to form a monovalent pooled harvest. An antimicrobial agent may be added at the time of harvest. At no stage in the production is penicillin or streptomycin used.

MONOVALENT POOLED HARVEST

To limit the possibility of contamination, inactivation is initiated as soon as possible after preparation. The virus is inactivated by a method that has been demonstrated on 3 consecutive batches to be consistently effective for the manufacturer. The inactivation process shall have been shown to be capable of inactivating the influenza virus without destroying its antigenicity; the process should cause minimum alteration of the haemagglutinin and neuraminidase antigens. The inactivation process shall also have been shown to be capable of inactivating avian leucosis viruses and mycoplasmas. If the monovalent pooled harvest is stored after inactivation, it is held at 5 ± 3 °C. If formaldehyde solution is used, the concentration does not exceed 0.2 g/l of CH₂O at any time during inactivation; if betapropiolactone is used, the concentration does not exceed 0.1 per cent V/V at any time during inactivation.

Before or after the inactivation process, the monovalent pooled harvest is concentrated and purified by high-speed centrifugation or other suitable method. Virus particles are disrupted into component subunits by approved procedures and further purified so that the monovalent bulk consists mainly of haemagglutinin and neuraminidase antigens.

Only a monovalent pooled harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Haemagglutinin antigen. Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it⁽²⁾. Carry out the test at 20-25 °C.

Neuraminidase antigen. The presence and type of neuraminidase antigen are confirmed by suitable enzymatic or immunological methods on the first 3 monovalent pooled harvests from each working seed lot.

Sterility (2.6.1). Carry out the test for sterility, using 10 ml for each medium.

Viral inactivation. Carry out the test described below under Tests.

Purity. The purity of the monovalent pooled harvest is examined by polyacrylamide gel electrophoresis or by other approved techniques. Mainly haemagglutinin and neuraminidase antigens shall be present.

Chemicals used for disruption and purification. Tests are carried out on the monovalent pooled harvest for the chemicals used for disruption and purification, the limits being approved by the competent authority.

FINAL BULK VACCINE

Appropriate quantities of the monovalent pooled harvests are blended to make the final bulk vaccine. An adjuvant may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

(2) Reference haemagglutinin antigens are available from the National Institute for Biological Standards and Control, Blanche Lane, South Mimms, Potters Bar, Hertfordshire EN6 3QG, Great Britain.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility, using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Tests and Assay may be released for use.

Provided that the test for viral inactivation has been performed with satisfactory results on each monovalent pooled harvest and that the tests for free formaldehyde, ovalbumin and total protein have been performed with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

If the ovalbumin and formaldehyde content cannot be determined on the final lot, owing to interference from the adjuvant, they are determined on the monovalent pooled harvest, the acceptance limits being set to ensure that the limits for the final product will not be exceeded.

If the vaccine contains an adjuvant, suitable tests for identity and other relevant quality criteria are carried out on the final lot. These tests may include chemical and physical analysis, determination of particle size and determination of the number of particles per unit volume.

IDENTIFICATION

The assay serves to confirm the antigenic specificity of the vaccine.

TESTS

Viral inactivation. Inoculate 0.2 ml of the vaccine into the allantoic cavity of each of 10 fertilised eggs and incubate at 33-37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest 0.5 ml of the allantoic fluid from each surviving embryo and pool the fluids. Inoculate 0.2 ml of the pooled fluid into a further 10 fertilised eggs and incubate at 33-37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest about 0.1 ml of the allantoic fluid from each surviving embryo and examine each individual harvest for live virus by a haemagglutination test. If haemagglutination is found for any of the fluids, carry out for that fluid a further passage in eggs and test for haemagglutination; no haemagglutination occurs.

Total protein. Not more than 40 µg of protein other than haemagglutinin per virus strain per human dose and not more than a total of 120 µg of protein other than haemagglutinin per human dose.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Ovalbumin. Not more than 1 µg of ovalbumin per human dose, determined by a suitable immunochemical method (2.7.1) using a suitable reference preparation of ovalbumin.

Sterility. It complies with the test for sterility (2.6.1).

Bacterial endotoxins (2.6.14): less than 100 IU per human dose.

ASSAY

Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it⁽²⁾. Carry out the test at 20-25 °C. The confidence limits ($P = 0.95$) are not less than 80 per cent and not more than 125 per cent of the estimated haemagglutinin antigen content. The lower confidence limit ($P = 0.95$) is not less than 80 per cent of the amount stated on the label for each strain.

LABELLING

The label states:

- that the vaccine has been prepared on eggs,
- the strain or strains of influenza virus used to prepare the vaccine,
- the method of inactivation,
- the haemagglutinin content in micrograms per virus strain per dose,
- the season during which the vaccine is intended to protect,
- where applicable, the name and the quantity of adjuvant used.

01/2005:2053

INFLUENZA VACCINE (SURFACE ANTIGEN, INACTIVATED, VIROSOME)

Vaccinum influenzae inactivatum ex corticis antigeniis praeparatum virosomale

DEFINITION

Influenza vaccine (surface antigen, inactivated, virosome) is a sterile, aqueous suspension of a strain or strains of influenza virus, type A or B, or a mixture of strains of the 2 types grown individually in fertilised hens' eggs, inactivated and treated so that the preparation consists predominantly of haemagglutinin and neuraminidase antigens reconstituted to virosomes with phospholipids and without diminishing the antigenic properties of the antigens. The stated amount of haemagglutinin antigen for each strain present in the vaccine is 15 µg per dose, unless clinical evidence supports the use of a different amount.

CHARACTERS

The vaccine is a slightly opalescent liquid.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

CHOICE OF VACCINE STRAIN

The World Health Organisation reviews the world epidemiological situation annually and if necessary recommends new strains corresponding to prevailing epidemiological evidence.

Such strains are used in accordance with the regulations in force in the signatory states of the Convention on the Elaboration of a European Pharmacopoeia. It is now common practice to use reassorted strains giving high yields

of the appropriate surface antigens. The origin and passage history of virus strains shall be approved by the competent authority.

SUBSTRATE FOR VIRUS PROPAGATION

Influenza virus seed to be used in the production of vaccine is propagated in fertilised eggs from chicken flocks free from specified pathogens (5.2.2) or in suitable cell cultures (5.2.4), such as chick-embryo fibroblasts or chick kidney cells obtained from chicken flocks free from specified pathogens (5.2.2). For production, the virus of each strain is grown in the allantoic cavity of fertilised hens' eggs from healthy flocks.

VIRUS SEED LOT

The production of vaccine is based on a seed lot system. Working seed lots represent not more than 15 passages from the approved reassorted virus or the approved virus isolate. The final vaccine represents 1 passage from the working seed lot. The haemagglutinin and neuraminidase antigens of each seed lot are identified as originating from the correct strain of influenza virus by suitable methods.

Only a working virus seed lot that complies with the following requirements may be used in the preparation of the monovalent pooled harvest.

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml for each medium.

Mycoplasmas (2.6.7). Carry out the test for mycoplasmas, using 10 ml.

VIRUS PROPAGATION AND HARVEST

An antimicrobial agent may be added to the inoculum. After incubation at a controlled temperature, the allantoic fluids are harvested and combined to form a monovalent pooled harvest. An antimicrobial agent may be added at the time of harvest.

MONOVALENT POOLED HARVEST

To limit the possibility of contamination, inactivation is initiated as soon as possible after preparation. The virus is inactivated by a method that has been demonstrated on 3 consecutive batches to be consistently effective for the manufacturer. The inactivation process shall have been shown to be capable of inactivating the influenza virus without destroying its antigenicity; the process is designed so as to cause minimum alteration of the haemagglutinin and neuraminidase antigens. The inactivation process shall also have been shown to be capable of inactivating avian leucosis viruses and mycoplasmas. If the monovalent pooled harvest is stored after inactivation, it is held at a temperature of 5 ± 3 °C. If formaldehyde solution is used, the concentration does not exceed 0.2 g/l of CH₂O at any time during inactivation; if betapropiolactone is used, the concentration does not exceed 0.1 per cent V/V at any time during inactivation.

Before or after the inactivation process, the monovalent pooled harvest is concentrated and purified by high-speed centrifugation or other suitable method.

Only a monovalent pooled harvest that complies with the following requirements may be used for the preparation of virosomes.

Haemagglutinin antigen. Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it⁽³⁾. Carry out the test at 20-25 °C.

Neuraminidase antigen. The presence and type of neuraminidase antigen are confirmed by suitable enzymatic or immunological methods on the first 3 monovalent pooled harvests from each working seed lot.

Viral inactivation. Carry out the test described under Tests.

PREPARATION OF MONOVALENT VIROSOMES

Virus particles are disrupted into component subunits by a suitable detergent and further purified so that the monovalent bulk consists mainly of haemagglutinin and neuraminidase antigens. After addition of suitable phospholipids, solubilisation by ultrasonication and sterile filtration, virosomal preparations are formed by removal of the detergent either by adsorption chromatography or another suitable technique. Several monovalent virosomal preparations may be pooled.

Only a monovalent virosomal preparation that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Haemagglutinin antigen. Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it⁽³⁾. Carry out the test at 20-25 °C.

Neuraminidase antigen. The presence and type of neuraminidase antigen are confirmed by suitable enzymatic or immunological methods on the first 3 virosomal preparations from each working seed lot.

Sterility (2.6.1). Carry out the test for sterility, using 10 ml for each medium.

Purity. The purity of the virosomal preparation is examined by polyacrylamide gel electrophoresis (2.2.31) or by other approved techniques. Mainly haemagglutinin and neuraminidase antigens are present.

Residual chemicals. Tests for the chemicals used for disruption and purification are carried out on the virosomal preparation, the limits being approved by the competent authority.

Phospholipid. The content and identity of the phospholipids is determined by suitable immunochemical or physico-chemical methods.

Ratio of haemagglutinin to phospholipid. The ratio of haemagglutinin content to phospholipid content is within the limits approved for the particular product.

Virosome size distribution. The size of the virosomes, determined by a suitable method such as laser light scattering, is not less than 100 nm and not greater than 500 nm.

FINAL BULK VACCINE

Appropriate quantities of the virosomal preparations are blended to make the final bulk vaccine.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility, using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

(3) Reference haemagglutinin antigens are available from the National Institute for Biological Standards and Control (NIBSC), Blanche Lane, South Mimms, Potters Bar, Hertfordshire EN6 3QC, United Kingdom.

Only a final lot that is satisfactory with respect to each of the requirements given under Tests and Assay may be released for use. Provided that the test for viral inactivation has been performed with satisfactory results on each monovalent pooled harvest and that the tests for phospholipid, ratio of haemagglutinin to phospholipid, free formaldehyde, ovalbumin and total protein have been performed with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

IDENTIFICATION

The assay serves to confirm the antigenic specificity of the vaccine.

TESTS

Viral inactivation. Inoculate 0.2 ml of the vaccine into the allantoic cavity of each of 10 fertilised eggs and incubate at 33-37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest 0.5 ml of the allantoic fluid from each surviving embryo and pool the fluids. Inoculate 0.2 ml of the pooled fluid into a further 10 fertilised eggs and incubate at 33-37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest about 0.1 ml of the allantoic fluid from each surviving embryo and examine each individual harvest for live virus by a haemagglutination test. If haemagglutination is found for any of the fluids, carry out for that fluid a further passage in eggs and test for haemagglutination; no haemagglutination occurs.

pH (2.2.3): 6.5 to 7.8

Total protein: maximum 40 µg of protein other than haemagglutinin per virus strain per human dose and maximum 120 µg of protein other than haemagglutinin per human dose.

Phospholipid. The content and identity of the phospholipids is determined by a suitable immunochemical or physico-chemical method.

Ratio of haemagglutinin to phospholipid. The ratio of haemagglutinin content to phospholipid content is within the limits approved for the particular product.

Free formaldehyde (2.4.18): where applicable, maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Ovalbumin: maximum 50 ng of ovalbumin per human dose, determined by a suitable technique using a suitable reference preparation of ovalbumin.

Sterility (2.6.1). It complies with the test for sterility.

Virosome size distribution. The size of the virosomes, determined by a suitable method such as laser light scattering, is not less than 100 nm and not greater than 500 nm.

Bacterial endotoxins (2.6.14): maximum 100 IU per human dose.

ASSAY

Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it⁽³⁾. Carry out the test at 20-25 °C. The confidence limits ($P = 0.95$) are not less than 80 per cent and not more than 125 per cent of

the estimated haemagglutinin antigen content. The lower confidence limit ($P = 0.95$) is not less than 80 per cent of the amount stated on the label for each strain.

LABELLING

The label states:

- that the vaccine has been prepared on eggs,
- the strain or strains of influenza virus used to prepare the vaccine,
- the method of inactivation,
- the haemagglutinin content, in micrograms per virus strain per dose,
- the season during which the vaccine is intended to protect.

01/2005:0159

INFLUENZA VACCINE (WHOLE VIRION, INACTIVATED)

*Vaccinum influenzae inactivatum
ex viris integris praeparatum*

DEFINITION

Influenza vaccine (whole virion, inactivated) is a sterile, aqueous suspension of a strain or strains of influenza virus, type A or B, or a mixture of strains of the two types grown individually in fertilised hens' eggs and inactivated in such a manner that their antigenic properties are retained. The stated amount of haemagglutinin antigen for each strain present in the vaccine is 15 µg per dose, unless clinical evidence supports the use of a different amount.

The vaccine is a slightly opalescent liquid.

PRODUCTION

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

CHOICE OF VACCINE STRAIN

The World Health Organisation reviews the world epidemiological situation annually and if necessary recommends new strains corresponding to prevailing epidemiological evidence.

Such strains are used in accordance with the regulations in force in the signatory states of the Convention on the Elaboration of a European Pharmacopoeia. It is now common practice to use reassorted strains giving high yields of the appropriate surface antigens. The origin and passage history of virus strains shall be approved by the competent authority.

SUBSTRATE FOR VIRUS PROPAGATION

Influenza virus seed to be used in the production of vaccine is propagated in fertilised eggs from chicken flocks free from specified pathogens (5.2.2) or in suitable cell cultures (5.2.4), such as chick-embryo fibroblasts or chick kidney cells obtained from chicken flocks free from specified pathogens (5.2.2). For production, the virus of each strain is grown in the allantoic cavity of fertilised hens' eggs from healthy flocks.

VIRUS SEED LOT

The production of vaccine is based on a seed-lot system. Working seed lots represent not more than 15 passages from the approved reassorted virus or the approved virus isolate. The final vaccine represents 1 passage from the working

seed lot. The haemagglutinin and neuraminidase antigens of each seed lot are identified as originating from the correct strain of influenza virus by suitable methods.

Only a working virus seed lot that complies with the following requirements may be used in the preparation of the monovalent pooled harvest.

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml for each medium.

Mycoplasmas (2.6.7). Carry out the test for mycoplasmas, using 10 ml.

VIRUS PROPAGATION AND HARVEST

An antimicrobial agent may be added to the inoculum. After incubation at a controlled temperature, the allantoic fluids are harvested and combined to form a monovalent pooled harvest. An antimicrobial agent may be added at the time of harvest. At no stage in the production is penicillin or streptomycin used.

MONOVALENT POOLED HARVEST

To limit the possibility of contamination, inactivation is initiated as soon as possible after preparation. The virus is inactivated by a method that has been demonstrated on three consecutive batches to be consistently effective for the manufacturer. The inactivation process shall have been shown to be capable of inactivating the influenza virus without destroying its antigenicity; the process should cause minimum alteration of the haemagglutinin and neuraminidase antigens. The inactivation process shall also have been shown to be capable of inactivating avian leucosis viruses and mycoplasmas. If the monovalent pooled harvest is stored after inactivation, it is held at a temperature of 5 ± 3 °C. If formaldehyde solution is used, the concentration does not exceed 0.2 g/l of CH₂O at any time during inactivation; if betapropiolactone is used, the concentration does not exceed 0.1 per cent V/V at any time during inactivation.

Before or after the inactivation process, the monovalent pooled harvest is concentrated and purified by high-speed centrifugation or other suitable method.

Only a monovalent pooled harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Haemagglutinin antigen. Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it⁽⁴⁾. Carry out the test at 20 °C to 25 °C.

Neuraminidase antigen. The presence and type of neuraminidase antigen are confirmed by suitable enzymatic or immunological methods on the first 3 monovalent pooled harvests from each working seed lot.

Sterility (2.6.1). Carry out the test for sterility, using 10 ml for each medium.

Viral inactivation. Carry out the test described below under Tests.

FINAL BULK VACCINE

Appropriate quantities of the monovalent pooled harvests are blended to make the final bulk vaccine.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Tests and Assay may be released for use. Provided that the test for viral inactivation has been performed with satisfactory results on each monovalent pooled harvest and that the tests for free formaldehyde, ovalbumin and total protein have been performed with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

IDENTIFICATION

The assay serves to confirm the antigenic specificity of the vaccine.

TESTS

Viral inactivation. Inoculate 0.2 ml of the vaccine into the allantoic cavity of each of 10 fertilised eggs and incubate at 33 °C to 37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest 0.5 ml of the allantoic fluid from each surviving embryo and pool the fluids. Inoculate 0.2 ml of the pooled fluid into a further 10 fertilised eggs and incubate at 33 °C to 37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest about 0.1 ml of the allantoic fluid from each surviving embryo and examine each individual harvest for live virus by a haemagglutination test. If haemagglutination is found for any of the fluids, carry out for that fluid a further passage in eggs and test for haemagglutination; no haemagglutination occurs.

Total protein. Not more than 6 times the total haemagglutinin content of the vaccine as determined in the assay, but in any case, not more than 100 µg of protein per virus strain per human dose and not more than a total of 300 µg of protein per human dose.

Ovalbumin. Not more than 1 µg of ovalbumin per human dose, determined by a suitable technique using a suitable reference preparation of ovalbumin.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). It complies with the test for sterility.

Bacterial endotoxins (2.6.14): less than 100 IU per human dose.

ASSAY

Determine the content of haemagglutinin antigen by an immunodiffusion test (2.7.1), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it⁽⁴⁾. Carry out the test at 20 °C to 25 °C. The confidence limits ($P = 0.95$) are not less than 80 per cent and not more than 125 per cent of

(4) Reference haemagglutinin antigens are available from the National Institute for Biological Standards and Control, Blanche Lane, South Mimms, Potters Bar, Hertfordshire EN6 3QG, Great Britain.

the estimated haemagglutinin antigen content. The lower confidence limit ($P = 0.95$) is not less than 80 per cent of the amount stated on the label for each strain.

LABELLING

The label states:

- that the vaccine has been prepared on eggs,
- the strain or strains of influenza virus used to prepare the vaccine,
- the method of inactivation,
- the haemagglutinin content in micrograms per virus strain per dose,
- the season during which the vaccine is intended to protect.

MEASLES, MUMPS AND RUBELLA VACCINE (LIVE)

Vaccinum morbillorum, parotitidis et rubellae vivum

DEFINITION

Measles, mumps and rubella vaccine (live) is a freeze-dried preparation of suitable attenuated strains of measles virus, mumps virus and rubella virus.

The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The three components are prepared as described in the monographs on *Measles vaccine (live)* (0213), *Mumps vaccine (live)* (0538) and *Rubella vaccine (live)* (0162) and comply with the requirements prescribed therein.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

FINAL BULK VACCINE

Virus harvests for each component are pooled and clarified to remove cells. A suitable stabiliser may be added and the pooled harvests diluted as appropriate. Suitable quantities of the pooled harvest for each component are mixed.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml for each medium.

FINAL LOT

For each component, a minimum virus concentration for release of the product is established such as to ensure, in the light of stability data, that the minimum concentration stated on the label will be present at the end of the period of validity.

Only a final lot that complies with the requirements for minimum virus concentration of each component for release, with the following requirement for thermal stability and with each of the requirements given below under Identification and Tests may be released for use. Provided that the tests for bovine serum albumin and, where applicable, for ovalbumin have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Thermal stability. Maintain samples of the final lot of freeze-dried vaccine in the dry state at 37 °C for 7 days. Determine the virus concentration as described under Assay in parallel for the heated vaccine and for unheated vaccine stored at 5 ± 3 °C. For each component, the virus concentration of the heated vaccine is not more than $1.0 \log_{10}$ lower than that of the unheated vaccine.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with antibodies specific for measles virus, mumps virus and rubella virus, it is no longer able to infect cell cultures susceptible to these viruses. When the vaccine reconstituted as stated on the label is mixed with quantities of specific antibodies sufficient to neutralise any two viral components, the third viral component infects susceptible cell cultures.

TESTS

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (2.6.1).

Bovine serum albumin. Not more than 50 ng per single human dose, determined by a suitable immunochemical method (2.7.1).

Ovalbumin. If the mumps component is produced in chick embryos, the vaccine contains not more than 1 µg of ovalbumin per single human dose, determined by a suitable immunochemical method (2.7.1).

Water (2.5.12). Not more than 3.0 per cent, determined by the semi-micro determination of water.

ASSAY

A. Mix the vaccine with a sufficient quantity of antibodies specific for mumps virus. Titrate the vaccine for infective measles virus at least in triplicate, using at least five cell cultures for each $0.5 \log_{10}$ dilution step or by a method of equal precision. Use an appropriate virus reference preparation to validate each assay. The estimated measles virus concentration is not less than that stated on the label; the minimum measles virus concentration stated on the label is not less than 1×10^3 CCID₅₀ per single human dose. The assay is not valid if the confidence interval ($P = 0.95$) of the logarithm of the virus concentration is greater than ± 0.3 .

Measles vaccine (live) BRP is suitable for use as a reference preparation.

B. Mix the vaccine with a sufficient quantity of antibodies specific for measles virus. Titrate the vaccine for infective mumps virus at least in triplicate, using at least five cell cultures for each $0.5 \log_{10}$ dilution step or by a method of equal precision. Use an appropriate virus reference preparation to validate each assay. The estimated mumps virus concentration is not less than that stated on the label; the minimum mumps virus concentration stated on the label is not less than 5×10^3 CCID₅₀ per single human dose. The assay is not valid if the confidence interval ($P = 0.95$) of the logarithm of the virus concentration is greater than ± 0.3 .

Mumps vaccine (live) BRP is suitable for use as a reference preparation.

C. Mix the vaccine with a sufficient quantity of antibodies specific for mumps virus. Titrate the vaccine for infective rubella virus at least in triplicate, using at least five cell cultures for each $0.5 \log_{10}$ dilution step or by a method of equal precision. Use an appropriate virus reference preparation to validate each assay. The estimated rubella virus concentration is not less than that stated on the label; the minimum rubella virus concentration stated on the label is not less than 1×10^3 CCID₅₀.

per single human dose. The assay is not valid if the confidence interval ($P = 0.95$) of the logarithm of the virus concentration is greater than ± 0.3 .

Rubella vaccine (live) BRP is suitable for use as a reference preparation.

LABELLING

The label states:

- the strains of virus used in the preparation of the vaccine,
- where applicable, that chick embryos have been used for the preparation of the vaccine,
- the type and origin of the cells used for the preparation of the vaccine,
- the minimum virus concentration for each component of the vaccine,
- that contact with disinfectants is to be avoided,
- the time within which the vaccine must be used after reconstitution,
- that the vaccine must not be given to a pregnant woman and that a woman must not become pregnant within 2 months after having the vaccine.

01/2005:0213
corrected

MEASLES VACCINE (LIVE)

Vaccinum morbillorum vivum

DEFINITION

Measles vaccine (live) is a freeze-dried preparation of a suitable attenuated strain of measles virus. The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The production of vaccine is based on a virus seed-lot system and, if the virus is propagated in human diploid cells, a cell-bank system. The production method shall have been shown to yield consistently live measles vaccines of adequate immunogenicity and safety in man. Unless otherwise justified and authorised, the virus in the final vaccine shall have undergone no more passages from the master seed lot than were used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy; even with authorised exceptions, the number of passages beyond the level used for clinical studies shall not exceed five.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in human diploid cells (5.2.3) or in cultures of chick-embryo cells derived from a chicken flock free from specified pathogens (5.2.2).

SEED LOT

The strain of measles virus used shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation. To avoid the unnecessary use of monkeys in the test for neurovirulence, virus seed lots are prepared in large quantities and stored at temperatures below -20°C if freeze-dried, or below -60°C if not freeze-dried.

Only a seed lot that complies with the following requirements may be used for virus propagation.

Identification. The master and working seed lots are identified as measles virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration of the master and working seed lots is determined to monitor consistency of production.

Extraneous agents (2.6.16). The working seed lot complies with the requirements for seed lots.

Neurovirulence (2.6.18). The working seed lot complies with the test for neurovirulence of live virus vaccines. *Macaca* and *Cercopithecus* monkeys susceptible to measles virus are suitable for the test.

PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Suitable animal (but not human) serum may be used in the growth medium, but the final medium for maintaining cell growth during virus multiplication does not contain animal serum. Serum and trypsin used in the preparation of cell suspensions and culture media are shown to be free from extraneous agents. The cell culture medium may contain a pH indicator such as phenol red and suitable antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during production. Not less than 500 ml of the production cell culture is set aside as uninfected cell cultures (control cells). The viral suspensions are harvested at a time appropriate to the strain of virus being used.

Only a single harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. The single harvest contains virus that is identified as measles virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration in the single harvest is determined as prescribed under Assay to monitor consistency of production and to determine the dilution to be used for the final bulk vaccine.

Extraneous agents (2.6.16). The single harvest complies with the tests for extraneous agents.

Control cells. If human diploid cells are used for production, the control cells comply with a test for identification. They comply with the tests for extraneous agents (2.6.16).

FINAL BULK VACCINE

Virus harvests that comply with the above tests are pooled and clarified to remove cells. A suitable stabiliser may be added and the pooled harvests diluted as appropriate.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Bacterial and fungal contamination. The final bulk vaccine complies with the test for sterility (2.6.1), carried out using 10 ml for each medium.

FINAL LOT

A minimum virus concentration for release of the product is established such as to ensure, in the light of stability data, that the minimum concentration stated on the label will be present at the end of the period of validity.

Only a final lot that complies with the requirements for minimum virus concentration for release, with the following requirement for thermal stability and with each of the requirements given below under Identification and Tests may be released for use. Provided that the test for bovine serum albumin has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Thermal stability. Maintain samples of the final lot of freeze-dried vaccine in the dry state at 37 °C for 7 days. Determine the virus concentration as described under Assay in parallel for the heated vaccine and for unheated vaccine stored at 5 ± 3 °C. The virus concentration of the heated vaccine is not more than 1.0 log₁₀ lower than that of the unheated vaccine.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with specific measles antibodies, it is no longer able to infect susceptible cell cultures.

TESTS

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (2.6.1).

Bovine serum albumin. Not more than 50 ng per single human dose, determined by a suitable immunochemical method (2.7.1).

Water (2.5.12). Not more than 3.0 per cent, determined by the semi-micro determination of water.

ASSAY

Titrate the vaccine for infective virus at least in triplicate, using at least five cell cultures for each 0.5 log₁₀ dilution step or by a method of equal precision. Use an appropriate virus reference preparation to validate each assay. The estimated virus concentration is not less than that stated on the label; the minimum virus concentration stated on the label is not less than 1 × 10³ CCID₅₀ per human dose. The assay is not valid if the confidence interval ($P = 0.95$) of the logarithm of the virus concentration is greater than ± 0.3.

Measles vaccine (live) BRP is suitable for use as a reference preparation.

LABELLING

The label states:

- the strain of virus used for the preparation of the vaccine,
- the type and origin of the cells used for the preparation of the vaccine,
- the minimum virus concentration,
- that contact with disinfectants is to be avoided,
- the time within which the vaccine must be used after reconstitution.

01/2005:2112

MENINGOCOCCAL GROUP C CONJUGATE VACCINE

*Vaccinum meningococcale classis C
coniugatum*

DEFINITION

Meningococcal group C conjugate vaccine is a liquid or freeze-dried preparation of purified capsular polysaccharide derived from a suitable strain of *Neisseria meningitidis* group C covalently linked to a carrier protein. Meningococcal group C polysaccharide consists of partly *O*-acetylated or *O*-deacetylated repeating units of sialic acids, linked with 2α→9 glycosidic bonds. The carrier protein, when conjugated to group C polysaccharide, is capable of inducing a T-cell-dependent B-cell immune response to the polysaccharide. The vaccine may contain an adjuvant.

PRODUCTION

GENERAL PROVISIONS

The production method shall consistently have been shown to yield meningococcal group C conjugate vaccines of satisfactory immunogenicity and safety in man. The production of meningococcal group C polysaccharide and of the carrier protein are based on seed-lot systems.

During development studies and wherever revalidation is necessary, a test for pyrogens in rabbits (2.6.8) is carried out by injection of a suitable dose of the final lot. The vaccine is shown to be acceptable with respect to absence of pyrogenic activity.

The production method is validated to demonstrate that the vaccine, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

During development studies and wherever revalidation of the manufacturing process is necessary, it shall be demonstrated by tests in animals that the vaccine consistently induces a T-cell-dependent B-cell immune response.

The stability of the final lot and relevant intermediates is evaluated using 1 or more indicator tests. Such tests may include determination of molecular size, determination of free saccharide in the conjugate or an immunogenicity test in animals.

BACTERIAL SEED LOTS

The bacterial strains used for master seed lots shall be identified by historical records that include information on their origin and the tests used to characterise the strain. Cultures from the working seed lot shall have the same characteristics as the strain that was used to prepare the master seed lot.

Purity of bacterial cultures is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

MENINGOCOCCAL GROUP C POLYSACCHARIDE

N. meningitidis is grown in a liquid medium that does not contain high-molecular-mass polysaccharides and is free from ingredients that will form a precipitate upon addition of cetyltrimethylammonium bromide (CTAB). The culture may be inactivated by heat and filtered before the polysaccharide is precipitated by addition of CTAB. The precipitate is further purified using suitable methods to remove nucleic acids, proteins and lipopolysaccharides and the final purification step consists of ethanol precipitation. An *O*-deacetylation step may also be included. Volatile matter, including water, in the purified polysaccharide is determined by a suitable method such as thermogravimetry (2.2.34). The value is used to calculate the results of other tests with reference to the dried substance, as prescribed below.

Only meningococcal group C polysaccharide that complies with the following requirements may be used in the preparation of the conjugate.

Protein (2.5.16): maximum 1.0 per cent, calculated with reference to the dried substance.

Nucleic acid (2.5.17): maximum 1.0 per cent, calculated with reference to the dried substance.

***O*-acetyl groups.** Examine by a suitable method (for example 2.5.19). An acceptable value is established for the particular product and each batch of meningococcal group C polysaccharide must be shown to comply with this limit.

Sialic acid (2.5.23): minimum 0.800 g of sialic acid per gram of meningococcal group C polysaccharide using *N*-acetylneuraminic acid *R* to prepare the reference solution.

Residual reagents. Where applicable, tests are carried out to determine residues of reagents used during inactivation and purification. An acceptable value for each reagent is established for the particular product and each batch of meningococcal group C polysaccharide must be shown to comply with this limit. Where validation studies have demonstrated removal of a residual reagent, the test on purified meningococcal group C polysaccharide may be omitted.

Molecular-size distribution. Examine by size-exclusion chromatography (2.2.30). An acceptable value is established for the particular product and each batch of meningococcal group C polysaccharide must be shown to comply with this limit. Where applicable, the molecular-size distribution is also determined after chemical modification of the meningococcal group C polysaccharide.

Identification and serological specificity. The identity and serological specificity are determined by a suitable immunochemical method (2.7.1) or other suitable method, for example ¹H nuclear magnetic resonance spectrometry (2.2.33).

Bacterial endotoxins (2.6.14): less than 100 IU per microgram of meningococcal group C polysaccharide.

CARRIER PROTEIN

The carrier protein is chosen so that when meningococcal group C polysaccharide is conjugated it is able to induce a T-cell-dependent immune response. Tetanus toxoid and the non-toxic mutant of diphtheria toxin-like protein, CRM197 are suitable. The carrier protein is produced by culture of a suitable microorganism, the bacterial purity of which is verified.

Only a carrier protein that complies with the following requirements may be used in preparation of the conjugate.

Identification. The carrier protein is identified by a suitable immunochemical method (2.7.1).

Diphtheria toxin-like protein. Where diphtheria toxin-like protein is used as the carrier, it contains not less than 90 per cent of CRM197, determined by a suitable method. Suitable tests are carried out, for validation or routinely, to demonstrate that the product is non-toxic.

Tetanus toxoid. Where tetanus toxoid is used as the carrier, it is produced as described in *Tetanus vaccine (adsorbed)* (0452) and complies with the requirements prescribed therein for bulk purified toxoid, except that the antigenic purity is not less than 1500 Lf per milligram of protein nitrogen.

BULK CONJUGATE

Meningococcal group C polysaccharide is chemically modified to enable conjugation; it is usually partly depolymerised either before or during this procedure. The conjugate is obtained by the covalent bonding of activated meningococcal group C oligosaccharide and carrier protein. The conjugate purification procedures are designed to remove residual reagents used for conjugation. The removal of residual reagents and reaction by-products is confirmed by suitable tests or by validation of the purification process. Only a bulk conjugate that complies with the following requirements may be used in the preparation of the final bulk vaccine. For each test and for each particular product, limits of acceptance are established and each batch of conjugate must be shown to comply with these limits.

Molecular-size distribution. Examine by size-exclusion chromatography (2.2.30). An acceptable value is established for the particular product and each batch of bulk conjugate must be shown to comply with this limit.

Saccharide. The saccharide content is determined by a suitable validated assay, for example (2.5.23). Anion-exchange liquid chromatography with pulsed amperometric detection (2.2.29) may also be used for determination of saccharide content. An acceptable value is established for the particular product and each batch of bulk conjugate must be shown to comply with this limit.

Protein. The protein content is determined by a suitable chemical method, for example (2.5.16). An acceptable value is established for the particular product and each batch of bulk conjugate must be shown to comply with this limit.

Saccharide-to-protein ratio. Determine the ratio by calculation.

Free saccharide. Unbound saccharide is determined after removal of the conjugate, for example by anion-exchange liquid chromatography, size-exclusion or hydrophobic chromatography, ultrafiltration or other validated methods. An acceptable value is established for the particular product and each batch of bulk conjugate must be shown to comply with this limit.

Free carrier protein. Determine the content, either directly by a suitable method or by deriving the content by calculation from the results of other tests. An acceptable value is established for the particular product and each batch of bulk conjugate must be shown to comply with this limit.

Residual reagents. Removal of residual reagents such as cyanide is confirmed by suitable tests or by validation of the process.

Sterility (2.6.1). It complies with the test for sterility, carried out using 10 ml for each medium or the equivalent of 100 doses, whichever is less.

FINAL BULK VACCINE

An adjuvant and a stabiliser may be added to the bulk conjugate before dilution to the final concentration with a suitable diluent.

Only a final bulk vaccine that complies with the following requirement and is within the limits approved for the particular product may be used in preparation of the final lot.

Sterility (2.6.1). It complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

Only a final lot that is within the limits approved for the particular product and is satisfactory with respect to each of the requirement given below under Identification, Tests and Assay may be released for use.

IDENTIFICATION

The vaccine is identified by a suitable immunochemical method (2.7.1).

TESTS

pH (2.2.3). The pH of the vaccine, reconstituted if necessary, is within ± 0.5 pH units of the limit approved for the particular product.

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Water (2.5.12): maximum 3.0 per cent for freeze-dried vaccines.

Free saccharide. Unbound saccharide is determined after removal of the conjugate, for example by anion-exchange liquid chromatography, size-exclusion or hydrophobic chromatography, ultrafiltration or other validated methods. An acceptable value consistent with adequate

immunogenicity, as shown in clinical trials, is established for the particular product and each final lot must be shown to comply with this limit.

Sterility (2.6.1). It complies with the test for sterility.

Bacterial endotoxins (2.6.14): less than 25 IU per single human dose.

ASSAY

Saccharide: minimum 80 per cent of the amount of meningococcal group C polysaccharide stated on the label. The saccharide content is determined by a suitable validated assay, for example sialic acid assay (2.5.23) or anion-exchange liquid chromatography with pulsed amperometric detection (2.2.29).

LABELLING

The label states:

- the number of micrograms of meningococcal group C polysaccharide per human dose,
- the type and number of micrograms of carrier protein per human dose.

01/2005:0250

MENINGOCOCCAL POLYSACCHARIDE VACCINE

Vaccinum meningococcale polysaccharidicum

DEFINITION

Meningococcal polysaccharide vaccine is a freeze-dried preparation of one or more purified capsular polysaccharides obtained from one or more suitable strains of *Neisseria meningitidis* group A, group C, group Y and group W135 that are capable of consistently producing polysaccharides.

N. meningitidis group A polysaccharide consists of partly *O*-acetylated repeating units of *N*-acetylmannosamine, linked with 1 α →6 phosphodiester bonds.

N. meningitidis group C polysaccharide consists of partly *O*-acetylated repeating units of sialic acid, linked with 2 α →9 glycosidic bonds.

N. meningitidis group Y polysaccharide consists of partly *O*-acetylated alternating units of sialic acid and D-glucose, linked with 2 α →6 and 1 α →4 glycosidic bonds.

N. meningitidis group W135 polysaccharide consists of partly *O*-acetylated alternating units of sialic acid and D-galactose, linked with 2 α →6 and 1 α →4 glycosidic bonds.

The polysaccharide component or components stated on the label together with calcium ions and residual moisture account for over 90 per cent of the mass of the preparation.

PRODUCTION

Production of the meningococcal polysaccharides is based on a seed-lot system. The production method shall have been shown to yield consistently meningococcal polysaccharide vaccines of satisfactory immunogenicity and safety in man. The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

SEED LOTS

The strains of *N. meningitidis* used for the master seed lots shall be identified by historical records that include information on their origin and by their biochemical and serological characteristics.

Cultures from each working seed lot shall have the same characteristics as the strain that was used to prepare the master seed lot. The strains have the following characteristics:

- colonies obtained from a culture are rounded, uniform in shape and smooth with a mucous, opalescent, greyish appearance,
- Gram staining reveals characteristic Gram-negative diplococci in “coffee-bean” arrangement,
- the oxidase test is positive,
- the culture utilises glucose and maltose,
- suspensions of the culture agglutinate with suitable specific antisera.

Purity of bacterial strains used for the seed lots is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

PROPAGATION AND HARVEST

The working seed lots are cultured on solid media that do not contain blood-group substances or ingredients of mammalian origin. The inoculum may undergo 1 or more subcultures in liquid medium before being used for inoculating the final medium. The liquid media used and the final medium are semisynthetic and free from substances precipitated by cetrimonium bromide (hexadecyltrimethylammonium bromide) and do not contain blood-group substances or high-molecular-mass polysaccharides.

The bacterial purity of the culture is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

The cultures are centrifuged and the polysaccharides precipitated from the supernatant by addition of cetrimonium bromide. The precipitate obtained is harvested and may be stored at –20 °C awaiting further purification.

PURIFIED POLYSACCHARIDES

The polysaccharides are purified, after dissociation of the complex of polysaccharide and cetrimonium bromide, using suitable procedures to remove successively nucleic acids, proteins and lipopolysaccharides.

The final purification step consists of ethanol precipitation of the polysaccharides which are then dried and stored at –20 °C. The loss on drying is determined by thermogravimetry (2.2.34) and the value is used to calculate the results of the other chemical tests with reference to the dried substance.

Only purified polysaccharides that comply with the following requirements may be used in the preparation of the final bulk vaccine.

Protein (2.5.16). Not more than 10 mg of protein per gram of purified polysaccharide, calculated with reference to the dried substance.

Nucleic acids (2.5.17). Not more than 10 mg of nucleic acids per gram of purified polysaccharide, calculated with reference to the dried substance.

***O*-Acetyl groups (2.5.19).** Not less than 2 mmol of *O*-acetyl groups per gram of purified polysaccharide for group A, not less than 1.5 mmol per gram of polysaccharide for group C, not less than 0.3 mmol per gram of polysaccharide for groups Y and W135, all calculated with reference to the dried substance.

Phosphorus (2.5.18). Not less than 80 mg of phosphorus per gram of group A purified polysaccharide, calculated with reference to the dried substance.

Sialic acid (2.5.23). Not less than 800 mg of sialic acid per gram of group C polysaccharide and not less than 560 mg of sialic acid per gram of purified polysaccharide for groups Y and W135, all calculated with reference to the dried substance. Use the following reference solutions.

Group C polysaccharide: a 150 mg/l solution of *N-acetylneuraminic acid R*.

Group Y polysaccharide: a solution containing 95 mg/l of *N-acetylneuraminic acid R* and 55 mg/l of *glucose R*.

Group W135 polysaccharide: a solution containing 95 mg/l of *N-acetylneuraminic acid R* and 55 mg/l of *galactose R*.

Calcium. If a calcium salt is used during purification, a determination of calcium is carried out on the purified polysaccharide; the content is within the limits approved for the particular product.

Distribution of molecular size. Examine by size-exclusion chromatography (2.2.30) using *agarose for chromatography R* or *cross-linked agarose for chromatography R*. Use a column about 0.9 m long and 16 mm in internal diameter equilibrated with a solvent having an ionic strength of 0.2 mol/kg and a pH of 7.0-7.5. Apply to the column about 2.5 mg of polysaccharide in a volume of about 1.5 ml and elute at about 20 ml/h. Collect fractions of about 2.5 ml and determine the content of polysaccharide by a suitable method. At least 65 per cent of group A polysaccharide, 75 per cent of group C polysaccharide, 80 per cent of group Y polysaccharide and 80 per cent of group W135 polysaccharide is eluted before a distribution coefficient (K_0) of 0.50 is reached. In addition, the percentages eluted before this distribution coefficient are within the limits approved for the particular product.

Identification and serological specificity. The identity and serological specificity are determined by a suitable immunochemical method (2.7.1). Identity and purity of each polysaccharide shall be confirmed; it shall be shown that there is not more than 1 per cent *m/m* of group-heterologous *N. meningitidis* polysaccharide.

Pyrogens (2.6.8). The polysaccharide complies with the test for pyrogens. Inject into each rabbit per kilogram of body mass 1 ml of a solution containing 0.025 µg of purified polysaccharide per millilitre.

FINAL BULK VACCINE

One or more purified polysaccharides of 1 or more *N. meningitidis* groups are dissolved in a suitable solvent that may contain a stabiliser. When dissolution is complete, the solution is filtered through a bacteria-retentive filter.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Sterility (2.6.1). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile containers. The containers are then closed so as to avoid contamination.

Only a final lot that is satisfactory with respect to each of the requirements prescribed below under Identification, Tests and Assay may be released for use.

CHARACTERS

A white or cream-coloured powder or pellet, freely soluble in water.

IDENTIFICATION

Carry out an identification test for each polysaccharide present in the vaccine by a suitable immunochemical method (2.7.1).

TESTS

Distribution of molecular size. Examine by size-exclusion chromatography (2.2.30). Use a column about 0.9 m long and 16 mm in internal diameter equilibrated with a solvent having an ionic strength of 0.2 mol/kg and a pH of 7.0-7.5. Apply to the column about 2.5 mg of each polysaccharide in a volume of about 1.5 ml and elute at about 20 ml/h. Collect fractions of about 2.5 ml and determine the content of polysaccharide by a suitable method.

For a divalent vaccine (group A + group C), use *cross-linked agarose for chromatography R*. The vaccine complies with the test if:

- 65 per cent of group A polysaccharide is eluted before $K_0 = 0.50$,
- 75 per cent of group C polysaccharide is eluted before $K_0 = 0.50$.

For a tetravalent vaccine (group A + group C + group Y + group W135), use *cross-linked agarose for chromatography R1* and apply a suitable immunochemical method (2.7.1) to establish the elution pattern of the different polysaccharides. The vaccine complies with the test if K_0 for the principal peak is:

- not greater than 0.70 for group A and group C polysaccharide,
- not greater than 0.57 for group Y polysaccharide,
- not greater than 0.68 for group W135 polysaccharide.

Water (2.5.12). Not more than 3.0 per cent, determined by the semi-micro determination of water.

Sterility (2.6.1). It complies with the test for sterility.

Pyrogens (2.6.8). It complies with the test for pyrogens. Inject per kilogram of the rabbit's mass 1 ml of a solution containing:

- 0.025 µg of polysaccharide for a monovalent vaccine,
- 0.050 µg of polysaccharide for a divalent vaccine,
- 0.10 µg of polysaccharide for a tetravalent vaccine.

ASSAY

Carry out an assay of each polysaccharide present in the vaccine.

For a divalent vaccine (group A + group C), use measurement of phosphorus (2.5.18) to determine the content of polysaccharide A and measurement of sialic acid (2.5.23) to determine the content of polysaccharide C. To determine sialic acid, use as reference solution a 150 mg/l solution of *N-acetylneuraminic acid R*.

For a tetravalent vaccine (group A + group C + group Y + group W135) a suitable immunochemical method (2.7.1) is used with a reference preparation of purified polysaccharide for each group.

The vaccine contains not less than 70 per cent and not more than 130 per cent of the quantity of each polysaccharide stated on the label.

LABELLING

The label states:

- the group or groups of polysaccharides (A, C, Y or W135) present in the vaccine,
- the number of micrograms of polysaccharide per human dose.

01/2005:0538
corrected**MUMPS VACCINE (LIVE)****Vaccinum parotitidis vivum****DEFINITION**

Mumps vaccine (live) is a freeze-dried preparation of a suitable attenuated strain of mumps virus. The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The production of vaccine is based on a virus seed-lot system and, if the virus is propagated in human diploid cells, a cell-bank system. The production method shall have been shown to yield consistently live mumps vaccines of adequate immunogenicity and safety in man. Unless otherwise justified and authorised, the virus in the final vaccine shall have undergone no more passages from the master seed lot than were used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy. The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in human diploid cells (5.2.3) or in chick-embryo cells or in the amniotic cavity of chick embryos derived from a chicken flock free from specified pathogens (5.2.2).

SEED LOT

The strain of mumps virus used shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation. To avoid the unnecessary use of monkeys in the test for neurovirulence, virus seed lots are prepared in large quantities and stored at temperatures below -20°C if freeze-dried, or below -60°C if not freeze-dried.

Only a seed lot that complies with the following requirements may be used for virus propagation.

Identification. The master and working seed lots are identified as mumps virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration of the master and working seed lots is determined to ensure consistency of production.

Extraneous agents (2.6.16). The working seed lot complies with the requirements for seed lots.

Neurovirulence (2.6.18). The working seed lot complies with the test for neurovirulence of live virus vaccines. *Macaca* and *Cercopithecus* monkeys are suitable for the test.

PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Suitable animal (but not human) serum may be used in the culture media. Serum and trypsin used in the preparation of cell suspensions and culture media are shown to be free from extraneous agents. The cell culture medium may contain a pH indicator such as phenol red and suitable antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during production. Not less than 500 ml of the production cell cultures is set aside as uninfected cell cultures (control

cells). If the virus is propagated in chick embryos, 2 per cent but not less than twenty eggs are set aside as uninfected control eggs. The viral suspensions are harvested at a time appropriate to the strain of virus being used.

Only a single harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. The single harvest contains virus that is identified as mumps virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration in the single harvest is determined as prescribed under Assay to monitor consistency of production and to determine the dilution to be used for the final bulk vaccine.

Extraneous agents (2.6.16). The single harvest complies with the tests for extraneous agents.

Control cells or eggs. If human diploid cells are used for production, the control cells comply with a test for identification; the control cells and the control eggs comply with the tests for extraneous agents (2.6.16).

FINAL BULK VACCINE

Single harvests that comply with the above tests are pooled and clarified to remove cells. A suitable stabiliser may be added and the pooled harvests diluted as appropriate.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Bacterial and fungal contamination. The final bulk vaccine complies with the test for sterility (2.6.1), carried out using 10 ml for each medium.

FINAL LOT

A minimum virus concentration for release of the product is established such as to ensure, in the light of stability data, that the minimum concentration stated on the label will be present at the end of the period of validity.

Only a final lot that complies with the requirements for minimum virus concentration for release, with the following requirement for thermal stability and with each of the requirements given below under Identification and Tests may be released for use. Provided that the tests for bovine serum albumin and, where applicable, for ovalbumin have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Thermal stability. Maintain samples of the final lot of freeze-dried vaccine in the dry state at 37°C for 7 days. Determine the virus concentration as described under Assay in parallel for the heated vaccine and for unheated vaccine stored at $5 \pm 3^{\circ}\text{C}$. The virus concentration of the heated vaccine is not more than $1.0 \log_{10}$ lower than that of the unheated vaccine.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with specific mumps antibodies, it is no longer able to infect susceptible cell cultures.

TESTS

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (2.6.1).

Bovine serum albumin. Not more than 50 ng per single human dose, determined by a suitable immunochemical method (2.7.1).

Ovalbumin. If the vaccine is produced in chick embryos, it contains not more than $1 \mu\text{g}$ of ovalbumin per single human dose, determined by a suitable immunochemical method (2.7.1).

Water (2.5.12). Not more than 3.0 per cent, determined by the semi-micro determination of water.

ASSAY

Titrate the vaccine for infective virus at least in triplicate, using at least five cell cultures for each 0.5 log₁₀ dilution step or by a method of equal precision. Use an appropriate virus reference preparation to validate each assay. The estimated virus concentration is not less than that stated on the label; the minimum virus concentration stated on the label is not less than 5×10^3 CCID₅₀ per human dose. The assay is not valid if the confidence interval ($P = 0.95$) of the logarithm of the virus concentration is greater than ± 0.3 .

Mumps vaccine (live) BRP is suitable for use as a reference preparation.

LABELLING

The label states:

- the strain of virus used for the preparation of the vaccine,
- that the vaccine has been prepared in chick embryos or the type and origin of cells used for the preparation of the vaccine,
- the minimum virus concentration,
- that contact with disinfectants is to be avoided,
- the time within which the vaccine must be used after reconstitution.

01/2005:0160

PERTUSSIS VACCINE

Vaccinum pertussis

DEFINITION

Pertussis vaccine is a sterile saline suspension of inactivated whole cells of one or more strains of *Bordetella pertussis*.

PRODUCTION

INACTIVATED *B. PERTUSSIS* SUSPENSION

The inactivated *B. pertussis* suspension is prepared as described in the monograph on *Pertussis vaccine (adsorbed) (0161)* and complies with the requirements prescribed therein.

FINAL BULK VACCINE

Suitable quantities of the inactivated single harvests are pooled to prepare the final bulk vaccine. Suitable antimicrobial preservatives may be added. The bacterial concentration of the final bulk vaccine does not exceed that corresponding to an opacity of 20 IU per single human dose. If 2 or more strains of *B. pertussis* are used, the composition of consecutive lots of the final bulk vaccine shall be consistent with respect to the proportion of each strain as measured in opacity units.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the tests for specific toxicity, free formaldehyde and antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

IDENTIFICATION

Identify pertussis vaccine by agglutination of the bacteria in the vaccine by antisera specific to *B. pertussis*.

TESTS

Specific toxicity. Use not fewer than 5 healthy mice each weighing 14 g to 16 g for the vaccine group and for the saline control. Use mice of the same sex or distribute males and females equally between the groups. Allow the animals access to food and water for at least 2 h before injection and during the test. Inject each mouse of the vaccine group intraperitoneally with 0.5 ml, containing a quantity of the vaccine equivalent to not less than half the single human dose. Inject each mouse of the control group with 0.5 ml of a 9 g/l sterile solution of *sodium chloride R*, preferably containing the same amount of antimicrobial preservative as that injected with the vaccine. Weigh the groups of mice immediately before the injection and 72 h and 7 days after the injection. The vaccine complies with the test if: (a) at the end of 72 h the total mass of the group of vaccinated mice is not less than that preceding the injection; (b) at the end of 7 days the average increase in mass per vaccinated mouse is not less than 60 per cent of that per control mouse; and (c) not more than 5 per cent of the vaccinated mice die during the test. The test may be repeated and the results of the tests combined.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

ASSAY

Carry out the assay of pertussis vaccine (2.7.7).

The estimated potency is not less than 4 IU per single human dose and the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 2 IU per single human dose.

LABELLING

The label states:

- the minimum number of International Units per single human dose,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:1356

PERTUSSIS VACCINE (ACELLULAR, COMPONENT, ADSORBED)

Vaccinum pertussis sine cellulis ex elementis praeparatum adsorbatum

DEFINITION

Pertussis vaccine (acellular, component, adsorbed) is a preparation of individually prepared and purified antigenic components of *Bordetella pertussis* adsorbed on a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate.

The vaccine contains either pertussis toxoid or a pertussis-toxin-like protein free from toxic properties, produced by expression of a genetically modified form of the corresponding gene. Pertussis toxoid is prepared from pertussis toxin by a method that renders the latter harmless while maintaining adequate immunogenic properties and avoiding reversion to toxin. The vaccine may also contain filamentous haemagglutinin, pertactin (a 69 kDa outer-membrane protein) and other defined components of *B. pertussis* such as fimbrial-2 and fimbrial-3 antigens. The latter 2 antigens may be copurified. The antigenic composition and characteristics are based on evidence of protection and freedom from unexpected reactions in the target group for which the vaccine is intended.

PRODUCTION

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

Where a genetically modified form of *B. pertussis* is used for production consistency and genetic stability shall be established in conformity with the requirements of the monograph *Products of recombinant DNA technology* (0784).

Reference vaccine. A batch of vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine is preferably stabilised by a method that has been shown to have no significant effect on the assay procedure when the stabilised and non-stabilised batches are compared.

CHARACTERISATION OF COMPONENTS

During development of the vaccine, the production process shall be validated to demonstrate that it yields consistently individual components that comply with the following requirements; after demonstration of consistency, the tests need not be applied routinely to each batch.

Adenylate cyclase. Not more than 500 ng in the equivalent of 1 dose of the final vaccine, determined by immunoblot analysis or another suitable method.

Tracheal cytotoxin. Not more than 2 pmol in the equivalent of 1 dose of the final vaccine, determined by a suitable method such as a biological assay or liquid chromatography (2.2.29).

Absence of residual dermonecrotic toxin. Inject intradermally into each of 3 unweaned mice, in a volume of 0.1 ml, the amount of component or antigenic fraction equivalent to 1 dose of the final vaccine. Observe for 48 h. No dermonecrotic reaction is demonstrable.

Specific properties. The components of the vaccine are analysed by one or more of the methods shown below in order to determine their identity and specific properties (activity per unit amount of protein) in comparison with reference preparations.

Pertussis toxin. Chinese hamster ovary (CHO) cell-clustering effect and haemagglutination as *in vitro* methods; lymphocytosis-promoting activity, histamine-sensitising activity and insulin secretory activity as *in vivo* methods. The toxin shows ADP-ribosyl transferase activity using transducin as the acceptor.

Filamentous haemagglutinin. Haemagglutination and inhibition by specific antibody.

Pertactin, fimbrial-2 and fimbrial-3 antigens. Reactivity with specific antibody.

Pertussis toxoid. The toxoid induces in animals production of antibodies capable of inhibiting all the properties of pertussis toxin.

PURIFIED COMPONENTS

Production of each component is based on a seed-lot system. The seed cultures from which toxin is prepared are managed to conserve or where necessary restore toxinogenicity by deliberate selection.

None of the media used at any stage contains blood or blood products of human origin. Media used for the preparation of seed lots and inocula may contain blood or blood products of animal origin.

Pertussis toxin and, where applicable, filamentous haemagglutinin and pertactin are purified and, after appropriate characterisation, detoxified using suitable chemical reagents, by a method that avoids reversion of the toxoid to toxin, particularly on storage or exposure to heat. Other components such as fimbrial-2 and fimbrial-3 antigens are purified either separately or together, characterised and shown to be free from toxic substances. The purification procedure is validated to demonstrate appropriate clearance of substances used during culture or purification.

The content of bacterial endotoxins (2.6.14) is determined to monitor the purification procedure and to limit the amount in the final vaccine. The limits applied for the individual components are such that the final vaccine contains less than 100 IU per single human dose.

Before detoxification, the purity of the components is determined by a suitable method such as polyacrylamide gel electrophoresis (PAGE) or liquid chromatography. SDS-PAGE or immunoblot analysis with specific monoclonal or polyclonal antibodies may be used to characterise subunits. Requirements are established for each individual product.

Only purified components that comply with the following requirements may be used in the preparation of the final bulk vaccine.

Sterility (2.6.1). Carry out the test for sterility using for each medium a quantity of purified component equivalent to not less than 100 doses.

Absence of residual pertussis toxin. *This test is not necessary for the product obtained by genetic modification.* Use a group of not fewer than 5 histamine-sensitive mice each weighing 18-26 g. Inject into each mouse the equivalent of 1 human dose intravenously or twice the human dose intraperitoneally, diluted to not more than 0.5 ml with phosphate-buffered saline solution containing 2 g/l of gelatin. Inject diluent into a second group of control mice.

After 5 days, inject 2 mg of histamine base intraperitoneally in a volume not exceeding 0.5 ml and observe for 24 h. If no animal dies, the preparation complies with the test.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

A validated test based on the clustering effect of the toxin for Chinese hamster ovary (CHO) cells may be used instead of the test in mice.

Residual detoxifying agents and other reagents. The content of residual detoxifying agents and other reagents is determined and shown to be below approved limits unless validation of the process has demonstrated acceptable clearance.

Antigen content. Determine the antigen content by a suitable immunochemical method (2.7.1) and protein nitrogen by sulphuric acid digestion (2.5.9) or another suitable method. The ratio of antigen content to protein nitrogen is within the limits established for the product.

FINAL BULK VACCINE

The vaccine is prepared by adsorption of suitable quantities of purified components, separately or together, onto aluminium hydroxide or hydrated aluminium phosphate. A suitable antimicrobial preservative may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the tests for absence of residual pertussis toxin and irreversibility of pertussis toxoid, antimicrobial preservative, free formaldehyde and the assay have been carried out with satisfactory results on the final bulk vaccine, these tests may be omitted on the final lot.

IDENTIFICATION

Subject the vaccine to a suitable desorption procedure such as the following: dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 10 g/l solution; maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. Examined by a suitable immunochemical method (2.7.1), the clear supernatant liquid reacts with specific antisera to the components stated on the label.

TESTS

Absence of residual pertussis toxin and irreversibility of pertussis toxoid. *This test is not necessary for the product obtained by genetic modification.* Use 3 groups each of not fewer than 5 histamine-sensitive mice. Inject intraperitoneally into the first group twice the single human dose of the vaccine stored at 2–8 °C. Inject intraperitoneally

into the second group twice the single human dose of the vaccine incubated at 37 °C for 4 weeks. Inject diluent into the third group of mice. After 5 days, inject into each mouse 2 mg of histamine base intraperitoneally in a volume not exceeding 0.5 ml and observe for 24 h. The test is invalid if 1 or more control mice die following histamine challenge. The vaccine complies with the test if no animal in the first or second group dies following histamine challenge. If 1 mouse dies in either or both of the first and second groups, the test may be repeated with the same number of mice or with a greater number and the results of valid tests combined; the vaccine complies with the test if, in both of the groups given the vaccine, not more than 5 per cent of the total number of mice die following histamine challenge.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject intravenously threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). It complies with the test for sterility.

ASSAY

The capacity of the vaccine to induce the formation of specific antibodies is compared with the same capacity of a reference preparation examined in parallel; antibodies are determined using suitable immunochemical methods (2.7.1) such as enzyme-linked immunosorbent assay (ELISA). The test in mice shown below uses a three-point model but, after validation, for routine testing a single-dilution method may be used.

Requirement. The capacity to induce antibodies is not significantly ($P = 0.95$) less than that of the reference vaccine.

The following test model is given as an example of a method that has been found to be satisfactory.

Selection and distribution of test animals. Use in the test healthy mice (for example, CD1 strain) of the same stock 4 to 8 weeks old. Distribute the animals in 6 groups of a number appropriate to the requirements of the assay. Use 3 dilutions of the vaccine to be examined and 3 dilutions of a reference preparation and attribute each dilution to a group of mice. Inject intraperitoneally or subcutaneously into each mouse 0.5 ml of the dilution attributed to its group.

Collection of serum samples. 4 to 5 weeks after vaccination, bleed the mice individually under anaesthesia. Store the sera at –20 °C until tested for antibody content.

Antibody determination. Assay the individual sera for content of specific antibodies to each component using a validated method such as the ELISA test shown below.

ELISA test. Microtitre plates (poly(vinyl chloride) or polystyrene as appropriate for the specific antigen) are coated with the purified antigen at a concentration of 100 ng per well. After washing, unreacted sites are blocked by incubating with a solution of bovine serum albumin and then

washed. Two-fold dilutions of sera from mice immunised with test or reference vaccines are made on the plates. After incubation at 22-25 °C for 1 h, the plates are washed. A suitable solution of anti-mouse IgG enzyme conjugate is added to each well and incubated at 22-25 °C for 1 h. After washing, a substrate is added from which the bound enzyme conjugate liberates a chromophore which can be quantified by measurement of absorbance (2.2.25). The test conditions are designed to obtain a linear response for absorbance with respect to antibody content over the range of measurement used and absorbance values within the range 0.1 to 2.0.

A reference antiserum of assigned potency is used in the test and serves as the basis for calculation of the antibody levels in test sera. A standardised control serum is also included in the test.

The test is not valid if:

- the value found for the control serum differs by more than 2 standard deviations from the assigned value,
- the confidence limits ($P = 0.95$) are less than 50 per cent or more than 200 per cent of the estimated potency.

Calculation. The antibody titres in the sera of mice immunised with reference and test vaccines are calculated and from the values obtained the potency of the test vaccine in relation to the reference vaccine is calculated by the usual statistical methods.

LABELLING

The label states:

- the names and amounts of the components present in the vaccine,
- where applicable, that the vaccine contains a pertussis toxin-like protein produced by genetic modification,
- the name and amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

corrected

PERTUSSIS VACCINE (ACELLULAR, CO-PURIFIED, ADSORBED)

Vaccinum pertussis sine cellulis
copurificatum adsorbatum

DEFINITION

Pertussis vaccine (acellular, co-purified, adsorbed) is a preparation of antigenic components of *Bordetella pertussis* adsorbed on a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate.

The vaccine contains an antigenic fraction purified without separation of the individual components. The antigenic fraction is treated by a method that transforms pertussis toxin to toxoid, rendering it harmless while maintaining adequate immunogenic properties of all the components and avoiding reversion to toxin. The antigenic fraction is composed of pertussis toxoid, filamentous haemagglutinin, pertactin (a 69 kDa outer-membrane protein) and other defined components of *B. pertussis* such as fimbrial-2 and fimbrial-3 antigens. It may contain residual pertussis toxin up to a maximum level approved by the competent authority. The antigenic composition and characteristics are based on evidence of protection and freedom from unexpected reactions in the target group for which the vaccine is intended.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

Reference vaccine. A batch of vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine is preferably stabilised, by a method that has been shown to have no significant effect on the assay procedure when the stabilised and non-stabilised batches are compared.

CHARACTERISATION OF COMPONENTS

During development of the vaccine, the production process shall be validated to demonstrate that it yields consistently an antigenic fraction that complies with the following requirements; after demonstration of consistency, the tests need not be applied routinely to each batch.

Adenylate cyclase. Not more than 500 ng in the equivalent of 1 dose of the final vaccine, determined by immunoblot analysis or another suitable method.

Tracheal cytotoxin. Not more than 2 pmol in the equivalent of 1 dose of the final vaccine, determined by a suitable method such as a biological assay or liquid chromatography (2.2.29).

Absence of residual dermonecrotic toxin. Inject intradermally into each of 3 unweaned mice, in a volume of 0.1 ml, the amount of antigenic fraction equivalent to 1 dose of the final vaccine. Observe for 48 h. No dermonecrotic reaction is demonstrable.

Specific properties. The antigenic fraction is analysed by one or more of the methods shown below in order to determine the identity and specific properties (activity per unit amount of protein) of its components in comparison with reference preparations.

Pertussis toxin. Chinese hamster ovary (CHO) cell-clustering effect and haemagglutination as *in vitro* methods; lymphocytosis-promoting activity, histamine-sensitising activity and insulin secretory activity as *in vivo* methods. The toxin shows ADP-ribosyl transferase activity using transducin as the acceptor.

Filamentous haemagglutinin. Haemagglutination and inhibition by specific antibody.

Pertactin, fimbrial-2 and fimbrial-3 antigens. Reactivity with specific antibody.

Pertussis toxoid. The toxoid induces in animals the production of antibodies capable of inhibiting all the properties of pertussis toxin.

PURIFIED ANTIGENIC FRACTION

Production of the antigenic fraction is based on a seed-lot system. The seed cultures are managed to conserve or, where necessary, restore toxinogenicity by deliberate selection. None of the media used at any stage contains blood or blood products of human origin. Media used for the preparation of seed batches and inocula may contain blood or blood products of animal origin.

The antigenic fraction is purified and, after appropriate characterisation, detoxified using suitable reagents by a method that ensures minimal reversion of toxoid to toxin, particularly on storage or exposure to heat. The purification procedure is validated to demonstrate appropriate clearance of substances used during culture or purification.

The content of bacterial endotoxins (2.6.14) is determined to monitor the purification procedure and to limit the amount in the final vaccine. The limits applied are such that the final vaccine contains not more than 100 IU per single human dose.

Before detoxification, the purity of the antigenic fraction is determined by a suitable method such as polyacrylamide gel electrophoresis (PAGE) or liquid chromatography. SDS-PAGE or immunoblot analysis with specific monoclonal or polyclonal antibodies may be used to characterise subunits. Requirements are established for each individual product.

Only a purified antigenic fraction that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Sterility (2.6.1). Carry out the test for sterility using for each medium a quantity of purified antigenic fraction equivalent to not less than 100 doses of the final vaccine.

Test for residual pertussis toxin. Use 3 groups of not fewer than 5 histamine-sensitive mice each weighing 18 g to 26 g. Using phosphate-buffered saline containing 2 g/l of gelatin, prepare a series of dilutions of the purified antigenic fraction that have been shown to yield a graded response and attribute each dilution to a separate group of mice. Inject intraperitoneally into each mouse the dilution attributed to its group. Inject diluent into a fourth group of control mice. After 5 days, inject intraperitoneally into each mouse 1 mg of histamine base in a volume not exceeding 0.5 ml. Record the number of animals that die within 24 h of histamine challenge. Calculate the weight or volume of a preparation that sensitises 50 per cent of the mice injected using a suitable statistical method such as probit analysis (see 5.3). The residual activity of pertussis toxin does not exceed that of batches shown to be safe in clinical studies.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as described above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

Pertussis toxin BRP is suitable for use as a reference pertussis toxin.

A validated test based on the clustering effect of the toxin for Chinese hamster ovary (CHO) cells may be used instead of the test in mice.

Residual detoxifying agents and other reagents. The content of residual detoxifying agents and other reagents is determined and shown to be below approved limits unless validation of the process has demonstrated acceptable clearance.

Antigen content. Determine the complete quantitative antigen composition of the antigenic fraction by suitable immunochemical methods (2.7.1) and protein nitrogen by sulphuric acid digestion (2.5.9) or another suitable method. The ratio of total antigen content to protein nitrogen is within the limits established for the product.

FINAL BULK VACCINE

The vaccine is prepared by adsorption of a suitable quantity of the antigenic fraction onto aluminium hydroxide or hydrated aluminium phosphate. A suitable antimicrobial preservative may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (2.6.1). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided that the tests for residual pertussis toxin, reversibility of toxoid, antimicrobial preservative, free formaldehyde and the assay have been carried out with satisfactory results on the final bulk vaccine, these tests may be omitted on the final lot.

IDENTIFICATION

Subject the vaccine to a suitable desorption procedure such as the following: dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 10 g/l solution; maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. Examined by a suitable immunochemical method (2.7.1), the clear supernatant liquid reacts with specific antisera to the components in the vaccine.

TESTS

Test for residual pertussis toxin. Use 3 groups of not fewer than 5 histamine-sensitive mice (see under Production) each weighing 18 g to 26 g. Using phosphate-buffered saline containing 2 g/l of gelatin, prepare a series of dilutions of the vaccine to be examined that have been shown to yield a graded response and attribute each dilution to a separate group of mice. Inject intraperitoneally into each mouse the dilution attributed to its group. Inject diluent into a fourth group of control mice. After 5 days, inject intraperitoneally into each mouse 1 mg of histamine base in a volume not exceeding 0.5 ml. Note the number of animals that die within 24 h of histamine challenge. Calculate the weight or volume of a preparation that sensitises 50 per cent of the mice injected using a suitable statistical method such as probit analysis (see 5.3). The residual activity of pertussis toxin does not exceed that of batches shown to be safe in clinical studies.

Reversibility of toxoid. Carry out the test for residual pertussis toxin described above using the vaccine incubated at 37 °C for 4 weeks in parallel with a sample stored at 2 °C to 8 °C. The degree of reversibility does not exceed that of batches shown to be safe in clinical studies.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Sterility (2.6.1). It complies with the test for sterility.

ASSAY

The vaccine complies with the assay of pertussis vaccine (acellular) (2.7.16).

LABELLING

The label states:

- the names and amounts of the antigenic components present in the vaccine,
- the maximum amount of residual pertussis toxin present in the vaccine,
- the maximum degree of reversion of toxoid to toxin during the period of validity,
- the name and amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:0161

PERTUSSIS VACCINE (ADSORBED)

Vaccinum pertussis adsorbatum

DEFINITION

Pertussis vaccine (adsorbed) is a sterile saline suspension of inactivated whole cells of one or more strains of *Bordetella pertussis* with a mineral adsorbent such as hydrated aluminium phosphate or aluminium hydroxide.

PRODUCTION

INACTIVATED *B. PERTUSSIS* SUSPENSION

Production is based on a seed-lot system. One or more strains of *B. pertussis* with known origin and history are used. Strains, culture medium and cultivation method are chosen in such a way that agglutinogens 1, 2 and 3 are present in the final vaccine. Each strain is grown for 24 h to 72 h in a liquid medium or on a solid medium; the medium used in the final cultivation stage does not contain blood or blood products. Human blood or blood products are not used in any culture media. The bacteria are harvested, washed to remove substances derived from the medium and suspended in a 9 g/l solution of sodium chloride or other suitable isotonic solution. The opacity of the suspension is determined not later than 2 weeks after harvest by comparison with the International Reference Preparation of Opacity and used as the basis of calculation for subsequent stages in vaccine preparation. The equivalence in International Units of the International Reference Preparation is stated by the World Health Organisation.

Single harvests are not used for the final bulk vaccine unless they have been shown to contain *B. pertussis* cells with the same characteristics, with regard to growth and agglutinogens, as the parent strain and to be free from contaminating bacteria and fungi. The bacteria are killed and detoxified in controlled conditions by means of a suitable chemical agent or by heating or by a combination of these methods. Freedom from live *B. pertussis* is tested using a suitable culture medium. The suspension is maintained at 5 ± 3 °C for a suitable period to diminish its toxicity.

FINAL BULK VACCINE

Suitable quantities of the inactivated single harvests are pooled to prepare the final bulk vaccine. A mineral adsorbent such as hydrated aluminium phosphate or aluminium hydroxide is added to the cell suspension. Suitable antimicrobial preservatives may be added. The bacterial concentration of the final bulk vaccine does not exceed that corresponding to an opacity of 20 IU per single human dose. If 2 or more strains of *B. pertussis* are used, the composition of consecutive lots of the final bulk vaccine shall be consistent with respect to the proportion of each strain as measured in opacity units.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the tests for specific toxicity, free formaldehyde and antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

IDENTIFICATION

Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge to obtain a bacterial precipitate. Other suitable methods for separating the bacteria from the adsorbent may also be used. Identify pertussis vaccine by agglutination of the bacteria from the resuspended precipitate by antisera specific to *B. pertussis* or by the assay.

TESTS

Specific toxicity. Use not fewer than 5 healthy mice each weighing 14 g to 16 g for the vaccine group and for the saline control. Use mice of the same sex or distribute males and females equally between the groups. Allow the animals access to food and water for at least 2 h before injection and during the test. Inject each mouse of the vaccine group intraperitoneally with 0.5 ml, containing a quantity of the vaccine equivalent to not less than half the single human dose. Inject each mouse of the control group with 0.5 ml of a 9 g/l sterile solution of *sodium chloride R*, preferably containing the same amount of antimicrobial preservative as that injected with the vaccine. Weigh the groups of mice immediately before the injection and 72 h and 7 days after the injection. The vaccine complies with the test if: (a) at the end of 72 h the total mass of the group of vaccinated mice is not less than that preceding the injection; (b) at the end of 7 days the average increase in mass per vaccinated mouse is not less than 60 per cent of that per control mouse; and (c) not more than 5 per cent of the vaccinated mice die during the test. The test may be repeated and the results of the tests combined.

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

ASSAY

Carry out the assay of pertussis vaccine (2.7.7).

The estimated potency is not less than 4 IU per single human dose and the lower confidence limit ($P = 0.95$) of the estimated potency is not less than 2 IU per single human dose.

LABELLING

The label states:

- the minimum number of International Units per single human dose,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:0966

PNEUMOCOCCAL POLYSACCHARIDE VACCINE

Vaccinum pneumococcale polysaccharidicum

DEFINITION

Pneumococcal polysaccharide vaccine consists of a mixture of equal parts of purified capsular polysaccharide antigens prepared from suitable pathogenic strains of *Streptococcus pneumoniae* whose capsules have been shown to be made up of polysaccharides that are capable of inducing satisfactory levels of specific antibodies in man. It contains the 23 immunochemically different capsular polysaccharides listed in Table 0966-1.

The vaccine is a clear, colourless liquid.

PRODUCTION

Production of the vaccine is based on a seed-lot system for each type. The production method shall have been shown to yield consistently pneumococcal polysaccharide vaccines of adequate safety and immunogenicity in man.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9) modified as follows for the test in guinea-pigs: inject 10 human doses into each guinea-pig and observe for 12 days.

MONOVALENT BULK POLYSACCHARIDES

The bacteria are grown in a suitable liquid medium that does not contain blood-group substances or high-molecular-mass polysaccharides. The bacterial purity of the culture is verified and the culture is inactivated with phenol. Impurities are removed by such techniques as fractional precipitation, enzymatic digestion and ultrafiltration. The polysaccharide is obtained by fractional precipitation, washed, and dried in a vacuum to a residual moisture content shown to be favourable to the stability of the polysaccharide. The residual moisture content is determined by drying under reduced pressure over diphosphorus pentoxide or by thermogravimetric analysis and the value obtained is used to calculate the results of the tests shown below with reference to the dried substance. The monovalent bulk polysaccharide is stored at a suitable temperature in conditions that avoid the uptake of moisture.

Only a monovalent bulk polysaccharide that complies with the following requirements may be used in the preparation of the final bulk vaccine. Percentage contents of components, determined by the methods prescribed below, are shown in Table 0966-1.

Protein (2.5.16).

Nucleic acids (2.5.17).

Total nitrogen (2.5.9).

Phosphorus (2.5.18).

Molecular size. Determine by size-exclusion chromatography (2.2.30) using *cross-linked agarose for chromatography R* or *cross-linked agarose for chromatography R1*.

Uronic acids (2.5.22).

Hexosamines (2.5.20).

Methylpentoses (2.5.21).

O-Acetyl groups (2.5.19).

Identification (2.7.1). Confirm the identity of the monovalent bulk polysaccharide by double immunodiffusion or electroimmunodiffusion (except for polysaccharides 7F, 14 and 33F), using specific antisera.

Specificity. No reaction occurs when the antigens are tested against all the antisera specific for the other polysaccharides of the vaccine, including factor sera for distinguishing types within groups. The polysaccharides are tested at a concentration of 50 µg/ml using a method capable of detecting 0.5 µg/ml.

FINAL BULK VACCINE

The final bulk vaccine is obtained by aseptically mixing the different polysaccharide powders. The uniform mixture is aseptically dissolved in a suitable isotonic solution so that one human dose of 0.50 ml contains 25 µg of each polysaccharide. An antimicrobial preservative may be added. The solution is sterilised by filtration through a bacteria-retentive filter.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). The final bulk vaccine complies with the test for sterility, using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers.

Only a final lot that is satisfactory with respect to each of the requirements given below under identification, tests and assay may be released for use. Provided that the tests for phenol and for antimicrobial preservative have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot. When consistency of production has been established on a suitable number of consecutive batches, the assay may be replaced by a qualitative test that identifies each polysaccharide, provided that an assay has been performed on each monovalent bulk polysaccharide used in the preparation of the final lot.

IDENTIFICATION

The assay serves also to identify the vaccine.

TESTS

pH (2.2.3). The pH of the vaccine is 4.5 to 7.4.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Phenol (2.5.15). Not more than 2.5 g/l.

Sterility (2.6.1). It complies with the test for sterility.

Table 0966.-1 – Percentage contents of components of monovalent bulk polysaccharides

Molecular type*	Protein	Nucleic acids	Total nitrogen	Phosphorus	Molecular size (K_0)		Uronic acids	Hexosamines	Methyl-pentoses	O-acetyl Groups
					**	***				
1	≤ 2	≤ 2	3.5-6	0-1.5	≤ 0.15		≥ 45			≥ 1.8
2	≤ 2	≤ 2	0-1	0-1.0	≤ 0.15		≥ 15		≥ 38	
3	≤ 5	≤ 2	0-1	0-1.0	≤ 0.15		≥ 40			
4	≤ 3	≤ 2	4-6	0-1.5	≤ 0.15			≥ 40		
5	≤ 7.5	≤ 2	2.5-6.0	≤ 2		≤ 0.60	≥ 12	≥ 20		
6B	≤ 2	≤ 2	0-2	2.5-5.0		≤ 0.50			≥ 15	
7F	≤ 5	≤ 2	1.5-4.0	0-1.0	≤ 0.20				≥ 13

20	≤ 2	≤ 2	0.5-2.5	1.5-4.0		≤ 0.60		≥ 12		
22F	≤ 2	≤ 2	0-2	0-1.0		≤ 0.55	≥ 15		≥ 25	
23F	≤ 2	≤ 2	0-1	3.0-4.5	≤ 0.15				≥ 37	
33F	≤ 2.5	≤ 2	0-2	0-1.0		≤ 0.50				

* The different types are indicated using the Danish nomenclature.

** Cross-linked agarose for chromatography R.

*** Cross-linked agarose for chromatography R1.

Pyrogens (2.6.8). It complies with the test for pyrogens. Inject per kilogram of the rabbit's mass 1 ml of a dilution of the vaccine containing 2.5 µg/ml of each polysaccharide.

01/2005:0214

POLIOMYELITIS VACCINE (INACTIVATED)

Vaccinum poliomyelitidis inactivatum

DEFINITION

Poliomyelitis vaccine (inactivated) is a liquid preparation of suitable strains of human polioviruses 1, 2 and 3 grown in suitable cell cultures and inactivated by a validated method. It is a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The production method shall have been shown to yield consistently vaccines of acceptable safety and immunogenicity in man.

Production of the vaccine is based on a virus seed-lot system. Cell lines are used according to a cell-bank system. If primary, secondary or tertiary monkey kidney cells are used, production complies with the requirements indicated below.

ASSAY

Determine the content of each polysaccharide by a suitable immunochemical method (2.7.1), using antisera specific for each polysaccharide contained in the vaccine, including factor sera for types within groups, and purified polysaccharides of each type as standards.

The vaccine contains not less than 70 per cent and not more than 130 per cent of the quantity stated on the label for each polysaccharide. The confidence limits ($P = 0.95$) are not less than 80 per cent and not more than 120 per cent of the estimated content.

LABELLING

The label states:

- the number of micrograms of each polysaccharide per human dose,
- the total amount of polysaccharide in the container.

Unless otherwise justified and authorised, the virus in the final vaccine shall not have undergone more passages from the master seed lot than was used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in a human diploid cell line (5.2.3), in a continuous cell line (5.2.3) or in primary, secondary or tertiary monkey kidney cells.

Primary, secondary or tertiary monkey kidney cells. The following special requirements for the substrate for virus propagation apply to primary, secondary or tertiary monkey kidney cells.

Monkeys used in the preparation of kidney cell cultures for production and control of the vaccine. The animals used are of a species approved by the competent authority, in good health and, unless otherwise justified and authorised, have not been previously employed for experimental purposes. Kidney cells used for vaccine production and control are derived from monitored, closed colonies of monkeys bred in captivity, not from animals caught in the wild; a previously approved seed lot prepared using virus passaged in cells from wild monkeys may, subject to approval by the competent authority, be used for vaccine production if historical data on safety justify this.

Monitored, closed colonies of monkeys. The monkeys are kept in groups in cages. Freedom from extraneous agents is achieved by the use of animals maintained in closed colonies that are subject to continuous and systematic veterinary and laboratory monitoring for the presence of infectious agents. The supplier of animals is certified by the competent authority. Each monkey is tested serologically at regular intervals during a quarantine period of not less than 6 weeks imposed before entering the colony and then during its stay in the colony.

The monkeys used are shown to be tuberculin-negative and free from antibodies to simian virus 40 (SV40) and simian immunodeficiency virus. The blood sample used in testing for SV40 antibodies must be taken as close as possible to the time of removal of the kidneys. If *Macaca* sp. monkeys are used for production, the monkeys are also shown to be free from antibodies to herpesvirus B (cercopithecine herpesvirus 1) infection. Human herpesvirus 1 has been used as an indicator for freedom from herpesvirus B antibodies on account of the danger of handling herpesvirus B (cercopithecine herpesvirus 1).

Monkeys from which kidneys are to be removed are thoroughly examined, particularly for evidence of tuberculosis and herpesvirus B (cercopithecine herpesvirus 1) infection. If a monkey shows any pathological lesion relevant to the use of its kidneys in the preparation of a seed lot or vaccine, it is not to be used nor are any of the remaining monkeys of the group concerned unless it is evident that their use will not impair the safety of the product.

All the operations described in this section are conducted outside the area where the vaccine is produced.

Monkey cell cultures for vaccine production. Kidneys that show no pathological signs are used for preparing cell cultures. Each group of cell cultures derived from a single monkey forms a separate production cell culture giving rise to a separate single harvest.

The primary monkey kidney cell suspension complies with the test for mycobacteria (2.6.2); disrupt the cells before carrying out the test.

If secondary or tertiary cells are used, it shall be demonstrated by suitable validation tests that cell cultures beyond the passage level used for production are free from tumorigenicity.

SEED LOTS

Each of the 3 strains of poliovirus used shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation.

Only a working seed lot that complies with the following requirements may be used for virus propagation.

Identification. Each working seed lot is identified as human poliovirus 1, 2 or 3 by virus neutralisation in cell culture using specific antibodies.

Virus concentration. The virus concentration of each working seed lot is determined to define the quantity of virus to be used for inoculation of production cell cultures.

Extraneous agents. The working seed lot complies with the requirements for seed lots for virus vaccines (2.6.16). In addition, if primary, secondary or tertiary monkey kidney cells have been used for isolation of the strain, measures are taken to ensure that the strain is not contaminated with simian viruses such as simian immunodeficiency virus, simian virus 40, filoviruses and herpesvirus B (cercopithecine herpesvirus 1). A working seed lot produced in primary, secondary or tertiary monkey kidney cells complies with the requirements given below under Virus propagation and harvest for single harvests produced in such cells.

PROPAGATION AND HARVEST

All processing of the cell bank and cell cultures is done under aseptic conditions in an area where no other cells or viruses are being handled. Approved animal serum (but not human serum) may be used in the cell culture media. Serum and trypsin used in the preparation of cell suspensions and media are shown to be free from extraneous agents. The cell culture media may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration. Not less than 500 ml of the cell cultures employed for vaccine production is set aside as uninfected cell cultures (control cells); where continuous cell lines in a fermenter are used for production, 200×10^6 cells are set aside to prepare control cells; where primary, secondary or tertiary monkey kidney cells are used for production, a cell sample equivalent to at least 500 ml of the cell suspension, at the concentration employed for vaccine production, is taken to prepare control cells.

Only a single harvest that complies with the following requirements may be used in the preparation of the vaccine. The tests for identification and bacterial and fungal contamination may be carried out instead on the purified, pooled monovalent harvest. After demonstration of consistency of production at the stage of the single harvest, the test for virus concentration may be carried out instead on the purified, pooled monovalent harvest.

Control cells. The control cells of the production cell culture comply with a test for identification (if a cell-bank system is used for production) and with the requirements for extraneous agents (2.6.16); where primary, secondary or tertiary monkey kidney cells are used, the tests in cell cultures are carried out as shown below under Test in rabbit kidney cell cultures and Test in cercopithecus kidney cell cultures).

- *Test in rabbit kidney cell cultures.* Test a sample of at least 10 ml of the pooled supernatant fluid from the control cultures for the absence of herpesvirus B (cercopithecine herpesvirus 1) and other viruses by inoculation onto rabbit kidney cell cultures. The dilution of supernatant in the nutrient medium is not

greater than 1/4 and the area of the cell layer is at least 3 cm² per millilitre of inoculum. Set aside one or more containers of each batch of cells with the same medium as non-inoculated control cells. Incubate the cultures at 37 °C and observe for at least 2 weeks. The test is not valid if more than 20 per cent of the control cells are discarded for non-specific, accidental reasons.

- **Test in cercopithecus kidney cell cultures.** Test a sample of at least 10 ml of the pooled supernatant fluid from the control cultures for the absence of SV40 virus and other extraneous agents by inoculation onto cell cultures prepared from the kidneys of cercopithecus monkeys, or other cells shown to be at least as sensitive for SV40, by the method described under Test in rabbit kidney cell cultures. The test is not valid if more than 20 per cent of the control cell cultures are discarded for non-specific, accidental reasons.

Identification. The single harvest is identified as containing human poliovirus 1, 2 or 3 by virus neutralisation in cell cultures using specific antibodies.

Virus concentration. The virus concentration of each single harvest is determined by titration of infectious virus in cell cultures.

Bacterial and fungal contamination. The single harvest complies with the test for sterility (2.6.1), carried out using 10 ml for each medium.

Mycoplasmas (2.6.7). The single harvest complies with the test for mycoplasmas, carried out using 10 ml.

Test in rabbit kidney cell cultures. Where primary, secondary or tertiary monkey kidney cells are used for production, test a sample of at least 10 ml of the single harvest for the absence of herpesvirus B (cercopithecine herpesvirus 1) and other viruses by inoculation onto rabbit kidney cell cultures as described above for the control cells.

Test in cercopithecus kidney cell cultures. Where primary, secondary or tertiary monkey kidney cells are used for production, test a sample of at least 10 ml of the single harvest for the absence of SV40 virus and other extraneous agents. Neutralise the sample by a high-titre antiserum against the specific type of poliovirus. Test the sample in primary cercopithecus kidney cell cultures or cells that have been demonstrated to be at least as susceptible for SV40. Incubate the cultures at 37 °C and observe for 14 days. At the end of this period, make at least one subculture of fluid in the same cell culture system and observe both primary cultures and subcultures for an additional 14 days.

PURIFICATION AND PURIFIED MONOVALENT HARVEST

Several single harvests of the same type may be pooled and may be concentrated. The monovalent harvest or pooled monovalent harvest is purified by validated methods. If continuous cell lines are used for production, the purification process shall have been shown to reduce consistently the content of substrate-cell DNA to not more than 100 pg per single human dose.

Only a purified monovalent harvest that complies with the following requirements may be used for the preparation of the inactivated monovalent harvest.

Identification. The virus is identified by virus neutralisation in cell cultures using specific antibodies or by determination of D-antigen.

Virus concentration. The virus concentration is determined by titration of infectious virus.

Specific activity. The ratio of the virus concentration or the D-antigen content, determined by a suitable immunochemical method (2.7.1), to the total protein content (specific activity) of the purified monovalent harvest is within the limits approved for the particular product.

INACTIVATION AND INACTIVATED MONOVALENT HARVEST

Several purified monovalent harvests of the same type may be mixed before inactivation. To avoid failures in inactivation caused by the presence of virus aggregates, filtration is carried out before and during inactivation; inactivation is started within a suitable period, preferably not more than 24 h and in any case not more than 72 h, of the prior filtration. The virus suspension is inactivated by a validated method that has been shown to inactivate poliovirus without destruction of immunogenicity; during validation studies, an inactivation curve with at least 4 points (for example, time 0 h, 24 h, 48 h and 96 h) is established showing the decrease in concentration of live virus with time. If formaldehyde is used for inactivation, the presence of an excess of formaldehyde at the end of the inactivation period is verified.

Only an inactivated monovalent harvest that complies with the following requirements may be used in the preparation of a trivalent pool of inactivated monovalent harvests or a final bulk vaccine.

Test for effective inactivation. After neutralisation of the formaldehyde with sodium bisulphite (where applicable), verify the absence of residual live poliovirus by inoculation on suitable cell cultures of 2 samples of each inactivated monovalent harvest, corresponding to at least 1500 human doses. Take one sample not later than three-quarters of the way through the inactivation period and the other at the end. Inoculate the samples in cell cultures such that the dilution of vaccine in the nutrient medium is not greater than 1/4 and the area of the cell layer is at least 3 cm² per millilitre of inoculum. Set aside one or more containers with the same medium as non-inoculated control cells. Observe the cell cultures for at least 3 weeks. Make not fewer than 2 passages from each container, one at the end of the observation period and the other 1 week before; for the passages, use cell culture supernatant and inoculate as for the initial sample. Observe the subcultures for at least 2 weeks. No sign of poliovirus multiplication is present in the cell cultures. At the end of the observation period, test the susceptibility of the cell culture used by inoculation of live poliovirus of the same type as that present in the inactivated monovalent harvest.

Sterility (2.6.1). The inactivated monovalent harvest complies with the test for sterility, carried out using 10 ml for each medium.

D-antigen content. The content of D-antigen determined by a suitable immunochemical method (2.7.1) is within the limits approved for the particular preparation.

FINAL BULK VACCINE

The final bulk vaccine is prepared directly from the inactivated monovalent harvests of human polioviruses 1, 2 and 3 or from a trivalent pool of inactivated monovalent harvests. If a trivalent pool of inactivated monovalent harvests is used, a test for effective inactivation is carried out on this pool instead of on the final bulk vaccine. A stabiliser and an antimicrobial preservative may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Sterility (2.6.1). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physicochemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Inactivation. Before addition of any antimicrobial preservative, a sample of at least 1500 ml or, for a purified and concentrated vaccine, the equivalent of 1500 doses is tested for residual live poliovirus in cell cultures, as described for the inactivated monovalent harvest. If the final bulk vaccine is prepared from a trivalent pool of inactivated monovalent harvests, the test for inactivation is carried out on that pool rather than on the final bulk vaccine.

FINAL LOT

Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the tests for free formaldehyde and antimicrobial preservative and the *in vivo* assay have been performed with satisfactory results on the final bulk vaccine, they may be omitted on the final lot. Provided that the test for bovine serum albumin has been performed with satisfactory results on the trivalent pool of inactivated monovalent harvests or on the final bulk vaccine, it may be omitted on the final lot.

IDENTIFICATION

The vaccine is shown to contain human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1) such as the determination of D-antigen by enzyme-linked immunosorbent assay (ELISA).

TESTS

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physicochemical method. The amount is not less than the minimum amount shown to be effective and is not greater than 115 per cent of that stated on the label.

Protein nitrogen content (Lowry method). Not more than 10 µg of protein nitrogen per single human dose.

Bovine serum albumin. Not more than 50 ng per single human dose, determined by a suitable immunochemical method (2.7.1).

Sterility (2.6.1). The vaccine complies with the test for sterility.

Bacterial endotoxins (2.6.14): less than 5 IU per single human dose.

ASSAY

D-antigen content. As a measure of consistency of production, determine the D-antigen content for human polioviruses 1, 2 and 3 by a suitable immunochemical method (2.7.1) using a reference preparation calibrated in European Pharmacopoeia D-antigen units. For each type, the content, expressed with reference to the amount of D-antigen stated on the label, is within the limits approved for the particular product.

Poliomyelitis vaccine (inactivated) BRP is calibrated in European Pharmacopoeia units and intended for use in the assay of D-antigen. The European Pharmacopoeia unit and the International Unit are equivalent.

In vivo test. The vaccine complies with the *in vivo* assay of poliomyelitis vaccine (inactivated) (2.7.20).

LABELLING

The label states:

- the types of poliovirus contained in the vaccine,
- the nominal amount of virus of each type (1, 2 and 3), expressed in Ph. Eur. units of D-antigen, per single human dose,
- the cell substrate used to prepare the vaccine.

01/2005:0215

POLIOMYELITIS VACCINE (ORAL)

Vaccinum poliomyelitidis perorale

DEFINITION

Oral poliomyelitis vaccine is a preparation of approved strains of live attenuated poliovirus type 1, 2 or 3 grown in *in vitro* cultures of approved cells, containing any one type or any combination of the 3 types of Sabin strains, presented in a form suitable for oral administration.

The vaccine is a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The vaccine strains and the production method shall have been shown to yield consistently vaccines that are both immunogenic and safe in man.

The production of vaccine is based on a virus seed-lot system. Cell lines are used according to a cell-bank system. If primary monkey kidney cell cultures are used, production complies with the requirements indicated below. Unless otherwise justified and authorised, the virus in the final vaccine shall not have undergone more than 2 passages from the master seed lot.

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in human diploid cells (5.2.3), in continuous cell lines (5.2.3) or in primary monkey kidney cell cultures (including serially passaged cells from primary monkey kidney cells).

Primary monkey kidney cell cultures. *The following special requirements for the substrate for virus propagation apply to primary monkey kidney cell cultures.*

Monkeys used for preparation of primary monkey kidney cell cultures and for testing of virus. If the vaccine is prepared in primary monkey kidney cell cultures, animals of a species approved by the competent authority, in good health, kept in closed or intensively monitored colonies and not previously employed for experimental purposes shall be used.

The monkeys shall be kept in well-constructed and adequately ventilated animal rooms in cages spaced as far apart as possible. Adequate precautions shall be taken to prevent cross-infection between cages. Not more than 2 monkeys shall be housed per cage and cage-mates shall not be interchanged. The monkeys shall be kept in the country of manufacture of the vaccine in quarantine groups for a period of not less than 6 weeks before use. A quarantine group is a colony of selected, healthy monkeys kept in one room, with separate feeding and cleaning facilities, and having no contact with other monkeys during the quarantine period. If at any time during the quarantine period the overall death rate of a shipment consisting of one or more groups reaches 5 per cent (excluding deaths from accidents or where the cause was specifically determined not to be an infectious disease), monkeys from that entire shipment shall continue in quarantine from that time for a minimum of 6 weeks. The groups shall be kept continuously in isolation, as in

quarantine, even after completion of the quarantine period, until the monkeys are used. After the last monkey of a group has been taken, the room that housed the group shall be thoroughly cleaned and decontaminated before being used for a fresh group. If kidneys from near-term monkeys are used, the mother is quarantined for the term of pregnancy.

Monkeys from which kidneys are to be removed shall be anaesthetised and thoroughly examined, particularly for evidence of tuberculosis and cercopithecoid herpesvirus 1 (B virus) infection.

If a monkey shows any pathological lesion relevant to the use of its kidneys in the preparation of a seed lot or vaccine, it shall not be used, nor shall any of the remaining monkeys of the quarantine group concerned be used unless it is evident that their use will not impair the safety of the product.

All the operations described in this section shall be conducted outside the areas where the vaccine is produced.

The monkeys used shall be shown to be free from antibodies to simian virus 40 (SV40), simian immunodeficiency virus and spumaviruses. The blood sample used in testing for SV40 antibodies must be taken as close as possible to the time of removal of the kidneys. If *Macaca* spp. are used for production, the monkeys shall also be shown to be free from antibodies to cercopithecoid herpesvirus 1 (B virus). Human herpesvirus has been used as an indicator for freedom from B virus antibodies on account of the danger of handling cercopithecoid herpesvirus 1 (B virus).

Primary monkey kidney cell cultures for vaccine production. Kidneys that show no pathological signs are used for preparing cell cultures. If the monkeys are from a colony maintained for vaccine production, serially passaged monkey kidney cell cultures from primary monkey kidney cells may be used for virus propagation, otherwise the monkey kidney cells are not propagated in series. Virus for the preparation of vaccine is grown by aseptic methods in such cultures. If animal serum is used in the propagation of the cells, the maintenance medium after virus inoculation shall contain no added serum.

Each group of cell cultures derived from a single monkey or from foetuses from no more than 10 near-term monkeys is prepared and tested as an individual group.

VIRUS SEED LOTS

The strains of poliovirus used shall be identified by historical records that include information on the origin and subsequent manipulation of the strains.

Working seed lots are prepared by a single passage from a master seed lot and at an approved passage level from the original Sabin virus. Virus seed lots are prepared in large quantities and stored at a temperature below -60°C .

Only a virus seed lot that complies with the following requirements may be used for virus propagation.

Identification. Each working seed lot is identified as poliovirus of the given type, using specific antibodies.

Virus concentration. Determined by the method described below, the virus concentration is the basis for the quantity of virus used in the neurovirulence test.

Extraneous agents (2.6.16). If the working seed lot is produced in human diploid cells or in a continuous cell line, it complies with the requirements for seed lots for virus vaccines. If the working seed lot is produced in primary monkey kidney cell cultures, it complies with the requirements given below under Virus Propagation and Harvest and Monovalent Pooled Harvest and with the tests

in adult mice, suckling mice and guinea-pigs given under 2.6.16. **Tests for extraneous agents in viral vaccines for human use.**

Working seed lots shall be free from detectable DNA sequences from simian virus 40 (SV40).

Neurovirulence (2.6.19). Each master and working seed lot complies with the test for neurovirulence of poliomyelitis vaccine (oral). Furthermore, the seed lot shall cease to be used in vaccine production if the frequency of failure of the monovalent pooled harvests produced from it is greater than predicted statistically. This statistical prediction is calculated after each test on the basis of all the monovalent pooled harvests tested; it is equal to the probability of false rejection on the occasion of a first test (i.e. 1 per cent), the probability of false rejection on retest being negligible. If the test is carried out only by the manufacturer, the test slides are provided to the control authority for assessment. Reference preparations of the 3 types of poliovirus at the Sabin Original + 2 passage levels are available on application to Biologicals, WHO, Geneva, Switzerland.

Genetic markers. Each working seed lot is tested for its replicating properties at temperatures ranging from 36°C to 40°C as described under Monovalent Pooled Harvest.

VIRUS PROPAGATION AND HARVEST

All processing of the cell banks and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Approved animal (but not human) serum may be used in the media, but the final medium for maintaining cell growth during virus multiplication does not contain animal serum. Serum and trypsin used in the preparation of cell suspensions and media are shown to be free from live extraneous agents. The cell-culture medium may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during production. On the day of inoculation with the virus working seed lot, not less than 5 per cent or 1000 ml, whichever is less, of the cell cultures employed for vaccine production are set aside as uninfected cell cultures (control cells); special requirements, given below, apply to control cells when the vaccine is produced in primary monkey kidney cell cultures. The virus suspension is harvested not later than 4 days after virus inoculation. After inoculation of the production cell culture with the virus working seed lot, inoculated cells are maintained at a fixed temperature, shown to be suitable, within the range 33°C to 35°C ; the temperature is maintained constant to $\pm 0.5^{\circ}\text{C}$; control cell cultures are maintained at $33-35^{\circ}\text{C}$ for the relevant incubation periods.

Only a single virus harvest that complies with the following requirements may be used in the preparation of the monovalent pooled harvest.

Virus concentration. The virus concentration of virus harvests is determined as prescribed under Assay to monitor consistency of production and to determine the dilution to be used for the final bulk vaccine.

Extraneous agents (2.6.16).

Control cells. The control cells of the production cell culture from which the virus harvest is derived comply with a test for identity and with the requirements for extraneous agents (2.6.16) or, where primary monkey kidney cell cultures are used, as shown below.

Primary monkey kidney cell cultures. The following special requirements apply to virus propagation and harvest in primary monkey kidney cell cultures.

Cell cultures. On the day of inoculation with virus working seed lot, each cell culture is examined for degeneration

caused by an infective agent. If, in this examination, evidence is found of the presence in a cell culture of any extraneous agent, the entire group of cultures concerned shall be rejected.

On the day of inoculation with the virus working seed lot, a sample of at least 30 ml of the pooled fluid removed from the cell cultures of the kidneys of each single monkey or from foetuses from not more than 10 near-term monkeys is divided into 2 equal portions. 1 portion of the pooled fluid is tested in monkey kidney cell cultures prepared from the same species, but not the same animal, as that used for vaccine production. The other portion of the pooled fluid is, where necessary, tested in monkey kidney cell cultures from another species so that tests on the pooled fluids are done in cell cultures from at least 1 species known to be sensitive to SV40. The pooled fluid is inoculated into bottles of these cell cultures in such a way that the dilution of the pooled fluid in the nutrient medium does not exceed 1 in 4. The area of the cell sheet is at least 3 cm²/ml of pooled fluid. At least 1 bottle of each kind of cell culture remains uninoculated to serve as a control. If the monkey species used for vaccine production is known to be sensitive to SV40, a test in a second species is not required. Animal serum may be used in the propagation of the cells, provided that it does not contain SV40 antibody, but the maintenance medium after inoculation of test material contains no added serum except as described below.

The cultures are incubated at a temperature of 35-37 °C and are observed for a total period of at least 4 weeks. During this observation period and after not less than 2 weeks' incubation, at least 1 subculture of fluid is made from each of these cultures in the same cell culture system. The subcultures are also observed for at least 2 weeks.

Serum may be added to the original culture at the time of subculturing, provided that the serum does not contain SV40 antibody.

Fluorescent-antibody techniques may be useful for detecting SV40 virus and other viruses in the cells.

A further sample of at least 10 ml of the pooled fluid is tested for cercopithecid herpesvirus 1 (B virus) and other viruses in rabbit kidney cell cultures. Serum used in the nutrient medium of these cultures shall have been shown to be free from inhibitors of B virus. Human herpesvirus has been used as an indicator for freedom from B virus inhibitors on account of the danger of handling cercopithecid herpesvirus 1 (B virus). The sample is inoculated into bottles of these cell cultures in such a way that the dilution of the pooled fluid in the nutrient medium does not exceed 1 in 4. The area of the cell sheet is at least 3 cm²/ml of pooled fluid. At least 1 bottle of the cell cultures remains uninoculated to serve as a control.

The cultures are incubated at a temperature of 35-37 °C and observed for at least 2 weeks.

A further sample of 10 ml of the pooled fluid removed from the cell cultures on the day of inoculation with the seed lot virus is tested for the presence of extraneous agents by inoculation into human cell cultures sensitive to measles virus.

The tests are not valid if more than 20 per cent of the culture vessels have been discarded for non-specific accidental reasons by the end of the respective test periods.

If, in these tests, evidence is found of the presence of an extraneous agent, the single harvest from the whole group of cell cultures concerned is rejected.

If the presence of cercopithecid herpesvirus 1 (B virus) is demonstrated, the manufacture of oral poliomyelitis vaccine shall be discontinued and the competent authority shall

be informed. Manufacturing shall not be resumed until a thorough investigation has been completed and precautions have been taken against any reappearance of the infection, and then only with the approval of the competent authority.

If these tests are not done immediately, the samples of pooled cell-culture fluid shall be kept at a temperature of -60 °C or below, with the exception of the sample for the test for B virus, which may be held at 4 °C, provided that the test is done not more than 7 days after it has been taken.

Control cell cultures. On the day of inoculation with the virus working seed lot, 25 per cent (but not more than 2.5 litres) of the cell suspension obtained from the kidneys of each single monkey or from not more than 10 near-term monkeys is taken to prepare uninoculated control cell cultures. These control cell cultures are incubated in the same conditions as the inoculated cultures for at least 2 weeks and are examined during this period for evidence of cytopathic changes. The tests are not valid if more than 20 per cent of the control cell cultures have been discarded for non-specific, accidental reasons. At the end of the observation period, the control cell cultures are examined for degeneration caused by an infectious agent. If this examination or any of the tests required in this section shows evidence of the presence in a control culture of any extraneous agent, the poliovirus grown in the corresponding inoculated cultures from the same group shall be rejected.

Tests for haemadsorbing viruses. At the time of harvest or within 4 days of inoculation of the production cultures with the virus working seed lot, a sample of 4 per cent of the control cell cultures is taken and tested for haemadsorbing viruses. At the end of the observation period, the remaining control cell cultures are similarly tested. The tests are made as described in 2.6.16. **Tests for extraneous agents in viral vaccines for human use.**

Tests for other extraneous agents. At the time of harvest, or within 7 days of the day of inoculation of the production cultures with the working seed lot, a sample of at least 20 ml of the pooled fluid from each group of control cultures is taken and tested in 2 kinds of monkey kidney cell culture, as described above.

At the end of the observation period for the original control cell cultures, similar samples of the pooled fluid are taken and the tests referred to in this section in the 2 kinds of monkey kidney cell culture and in the rabbit cell cultures are repeated, as described above under Cell cultures.

If the presence of cercopithecid herpesvirus 1 (B virus) is demonstrated, the production cell cultures shall not be used and the measures concerning vaccine production described above must be undertaken.

The fluids collected from the control cell cultures at the time of virus harvest and at the end of the observation period may be pooled before testing for extraneous agents. A sample of 2 per cent of the pooled fluid is tested in each of the cell culture systems specified.

Single harvests.

Tests for neutralised single harvests in primary monkey kidney cell cultures. A sample of at least 10 ml of each single harvest is neutralised by a type-specific poliomyelitis antiserum prepared in animals other than monkeys. In preparing antisera for this purpose, the immunising antigens used shall be prepared in non-simian cells.

Half of the neutralised suspension (corresponding to at least 5 ml of single harvest) is tested in monkey kidney cell cultures prepared from the same species, but not the same animal, as that used for vaccine production. The other half of the neutralised suspension is tested, if necessary, in monkey

kidney cell cultures from another species so that the tests on the neutralised suspension are done in cell cultures from at least 1 species known to be sensitive to SV40.

The neutralised suspensions are inoculated into bottles of these cell cultures in such a way that the dilution of the suspension in the nutrient medium does not exceed 1 in 4. The area of the cell sheet is at least 3 cm²/ml of neutralised suspension. At least 1 bottle of each type of cell culture remains uninoculated to serve as a control and is maintained by nutrient medium containing the same concentration of the specific antiserum used for neutralisation.

Animal serum may be used in the propagation of the cells, provided that it does not contain SV40 antibody, but the maintenance medium, after the inoculation of the test material, contains no added serum other than the poliovirus neutralising antiserum, except as described below.

The cultures are incubated at a temperature of 35-37 °C and observed for a total period of at least 4 weeks. During this observation period and after not less than 2 weeks' incubation, at least 1 subculture of fluid is made from each of these cultures in the same cell-culture system. The subcultures are also observed for at least 2 weeks.

Serum may be added to the original cultures at the time of subculturing, provided that the serum does not contain SV40 antibody.

Additional tests are made for extraneous agents on a further sample of the neutralised single harvests by inoculation of 10 ml into human cell cultures sensitive to measles virus.

Fluorescent-antibody techniques may be useful for detecting SV40 virus and other viruses in the cells.

The tests are not valid if more than 20 per cent of the culture vessels have been discarded for non-specific accidental reasons by the end of the respective test periods.

If any cytopathic changes occur in any of the cultures, the causes of these changes are investigated. If the cytopathic changes are shown to be due to unneutralised poliovirus, the test is repeated. If there is evidence of the presence of SV40 or other extraneous agents attributable to the single harvest, that single harvest is rejected.

MONOVALENT POOLED HARVEST

Monovalent pooled harvests are prepared by pooling a number of satisfactory single harvests of the same virus type. Monovalent pooled harvests from continuous cell lines may be purified. Each monovalent pooled harvest is filtered through a bacteria-retentive filter.

Only a monovalent pooled harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. Each monovalent pooled harvest is identified as poliovirus of the given type, using specific antibodies.

Virus concentration. The virus concentration is determined by the method described below and serves as the basis for calculating the dilutions for preparation of the final bulk, for the quantity of virus used in the neurovirulence test and to establish and monitor production consistency.

Genetic markers. A ratio of the replication capacities of the virus in the monovalent pooled harvest is obtained over a temperature range between 36 °C and 40 °C in comparison with the seed lot or a reference preparation for the marker tests and with appropriate rct/40- and rct/40+ strains of poliovirus of the same type. The incubation temperatures used in this test are controlled to within ± 0.1 °C. The monovalent pooled harvest passes the test if, for both the virus in the harvest and the appropriate reference material, the titre determined at 36 °C is at least 5.0 log greater than

that determined at 40 °C. If growth at 40 °C is so low that a valid comparison cannot be established, a temperature in the region of 39.0 °C to 39.5 °C is used, at which temperature the reduction in titre of the reference material must be in the range 3.0 to 5.0 log of its value at 36 °C; the acceptable minimum reduction is determined for each virus strain at a given temperature. If the titres obtained for 1 or more of the reference viruses are not concordant with the expected values, the test must be repeated.

Neurovirulence (2.6.19). Each monovalent pooled harvest complies with the test for neurovirulence of poliomyelitis vaccine (oral). If the test is carried out only by the manufacturer, the test slides are provided to the competent authority for assessment.

Primary monkey kidney cell cultures. *The following special requirements apply to monovalent pooled harvests derived from primary monkey kidney cell cultures.*

Retroviruses. The monovalent pooled harvest is examined using a reverse transcriptase assay. No indication of the presence of retroviruses is found.

Test in rabbits. A sample of the monovalent pooled harvest is tested for cercopithecid herpesvirus 1 (B virus) and other viruses by injection of not less than 100 ml into not fewer than 10 healthy rabbits each weighing 1.5-2.5 kg. Each rabbit receives not less than 10 ml and not more than 20 ml, of which 1 ml is given intradermally at multiple sites, and the remainder subcutaneously. The rabbits are observed for at least 3 weeks for death or signs of illness.

All rabbits that die after the first 24 h of the test and those showing signs of illness are examined by autopsy, and the brain and organs removed for detailed examination to establish the cause of death.

The test is not valid if more than 20 per cent of the inoculated rabbits show signs of intercurrent infection during the observation period. The monovalent pooled harvest passes the test if none of the rabbits shows evidence of infection with B virus or with other extraneous agents or lesions of any kind attributable to the bulk suspension.

If the presence of B virus is demonstrated, the measures concerning vaccine production described above under Cell cultures are taken.

Test in guinea-pigs. *If the primary monkey kidney cell cultures are not derived from monkeys kept in a closed colony, the monovalent pooled harvest shall be shown to comply with the following test.* Administer to not fewer than 5 guinea-pigs, each weighing 350-450 g, 0.1 ml of the monovalent pooled harvest by intracerebral injection and 0.5 ml by intraperitoneal injection. Measure the rectal temperature of each animal on each working day for 6 weeks. At the end of the observation period carry out autopsy on each animal.

In addition, administer to not fewer than 5 guinea-pigs 0.5 ml by intraperitoneal injection and observe as described above for 2-3 weeks. At the end of the observation period, carry out a passage from these animals to not fewer than 5 guinea-pigs using blood and a suspension of liver or spleen tissue. Measure the rectal temperature of the latter guinea-pigs for 2-3 weeks. Examine by autopsy all animals that, after the first day of the test, die or are killed because they show disease or show on 3 consecutive days a body temperature higher than 40.1 °C; carry out histological examination to detect infection with filoviruses; in addition, inject a suspension of liver or spleen tissue or of blood intraperitoneally into not fewer than 3 guinea-pigs. If any signs of infection with filoviruses are noted, confirmatory serological tests are carried out on the blood of the affected animals. The monovalent pooled harvest complies with the

01/2005:0216

test if not fewer than 80 per cent of the guinea-pigs survive to the end of the observation period and remain in good health and no animal shows signs of infection with filoviruses.

FINAL BULK VACCINE

The final bulk vaccine is prepared from one or more satisfactory monovalent pooled harvests and may contain more than one virus type. Suitable flavouring substances and stabilisers may be added.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml for each medium.

FINAL LOT

Only a final lot that complies with the following requirement for thermal stability and is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Thermal stability. Maintain samples of the final lot at 37 °C for 48 h. Determine the total virus concentration as described under Assay in parallel for the heated vaccine and for unheated vaccine. The estimated difference between the total virus concentration of the unheated and heated vaccines is not greater than 0.5 log₁₀ infectious virus units (CCID₅₀) per single human dose.

IDENTIFICATION

The vaccine is shown to contain poliovirus of each type stated on the label, using specific antibodies.

TESTS

Bacterial and fungal contamination. The vaccine complies with the test for sterility (2.6.1).

ASSAY

Titrate for infectious virus at least in triplicate using the method described below. Use an appropriate virus reference preparation to validate each assay. If the vaccine contains more than one poliovirus type, titrate each type separately, using appropriate type-specific antiserum (or preferably a monoclonal antibody) to neutralise each of the other types present.

For a trivalent vaccine, the estimated mean virus titres must be: not less than $1 \times 10^{6.0}$ infectious virus units (CCID₅₀) per single human dose for type 1; not less than $1 \times 10^{5.0}$ infectious virus units (CCID₅₀) for type 2; and not less than $1 \times 10^{5.5}$ infectious virus units (CCID₅₀) for type 3.

For monovalent or divalent vaccine, the minimum virus titres are decided by the competent authority.

Method. Inoculate groups of 8 to 12 flat-bottomed wells in a microtitre plate with 0.1 ml of each of the selected dilutions of virus followed by a suitable cell suspension of the Hep-2 (Cincinnati) line. Incubate the plates at a suitable temperature. Examine the cultures on days 7-9. The assay is not valid if the confidence interval ($P = 0.95$) of the logarithm of the virus concentration is greater than ± 0.3 .

LABELLING

The label states:

- the types of poliovirus contained in the vaccine,
- the minimum amount of virus of each type contained in 1 single human dose,
- the cell substrate used for the preparation of the vaccine,
- that the vaccine is not to be injected.

RABIES VACCINE FOR HUMAN USE PREPARED IN CELL CULTURES

Vaccinum rabiei ex cellulis ad usum humanum

DEFINITION

Rabies vaccine for human use prepared in cell cultures is a freeze-dried preparation of a suitable strain of fixed rabies virus grown in cell cultures and inactivated by a validated method.

The vaccine is reconstituted immediately before use as stated on the label to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The production of the vaccine is based on a virus seed-lot system and, if a cell line is used for virus propagation, a cell-bank system. The production method shall have been shown to yield consistently vaccines that comply with the requirements for immunogenicity, safety and stability. Unless otherwise justified and authorised, the virus in the final vaccine shall not have undergone more passages from the master seed lot than was used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy; even with authorised exceptions, the number of passages beyond the level used for clinical studies shall not exceed five.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in a human diploid cell line (5.2.3), in a continuous cell line approved by the competent authority or in cultures of chick-embryo cells derived from a flock free from specified pathogens (5.2.2).

SEED LOTS

The strain of rabies virus used shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation.

Working seed lots are prepared by not more than five passages from the master seed lot.

Only a working seed lot that complies with the following tests may be used for virus propagation.

Identification. Each working seed lot is identified as rabies virus using specific antibodies.

Virus concentration. The virus concentration of each working seed lot is determined by a cell culture method using immunofluorescence, to ensure consistency of production.

Extraneous agents (2.6.16). The working seed lot complies with the requirements for virus seed lots. If the virus has been passaged in mouse brain, specific tests for murine viruses are carried out.

VIRUS PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures are done under aseptic conditions in an area where no other cells are handled. Approved animal (but not human) serum may be used in the media, but the final medium for maintaining cell growth during virus multiplication does not contain animal serum; the media may contain human albumin complying with the monograph on *Human albumin solution* (0255). Serum and trypsin used in the preparation of cell suspensions and media are shown to be free from

infectious extraneous agents; trypsin complies with the monograph on *Trypsin* (0694). The cell culture media may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration. Not less than 500 ml of the cell cultures employed for vaccine production are set aside as uninfected cell cultures (control cells). The virus suspension is harvested on one or more occasions during incubation. Multiple harvests from the same production cell culture may be pooled and considered as a single harvest.

Only a single harvest that complies with the following requirements may be used in the preparation of the inactivated viral harvest.

Identification. The single harvest contains virus that is identified as rabies virus using specific antibodies.

Virus concentration. Titrate for infective virus in cell cultures; the titre is used to monitor consistency of production.

Control cells. The control cells of the production cell culture from which the single harvest is derived comply with a test for identification and with the requirements for extraneous agents (2.6.16).

PURIFICATION AND INACTIVATION

The virus harvest may be concentrated and/or purified by suitable methods; the virus harvest is inactivated by a validated method at a fixed, well defined stage of the process which may be before, during or after any concentration or purification. The method shall have been shown to be capable of inactivating rabies virus without destruction of the immunogenic activity. If betapropiolactone is used, the concentration shall at no time exceed 1:3500.

Only an inactivated viral suspension that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Inactivation. Carry out an amplification test for residual infectious rabies virus immediately after inactivation or using a sample frozen immediately after inactivation and stored at -70°C . Inoculate a quantity of inactivated viral suspension equivalent to not less than 25 doses of vaccine into cell cultures of the same type as those used for production of the vaccine. Make a passage after 7 days. Maintain the cultures for a further 14 days and then examine the cell cultures for rabies virus using an immunofluorescence test. No rabies virus is detected.

Residual host-cell DNA. If a continuous cell line is used for virus propagation, the content of residual host-cell DNA, determined using a suitable method as described in *Products of recombinant DNA technology* (0784), is not greater than 100 pg per single human dose.

FINAL BULK VACCINE

The final bulk vaccine is prepared from one or more inactivated viral suspensions. An approved stabiliser may be added to maintain the activity of the product during and after freeze-drying.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Glycoprotein content. Determine the glycoprotein content by a suitable immunochemical method (2.7.1), for example, single-radial immunodiffusion, enzyme-linked immunosorbent assay or an antibody-binding test. The content is within the limits approved for the particular product.

Sterility (2.6.1). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile containers and freeze-dried to a moisture content shown to be favourable to the stability of the vaccine. The containers are then closed so as to avoid contamination and the introduction of moisture.

Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the test for inactivation has been carried out with satisfactory results on the inactivated viral suspension and the test for bovine serum albumin has been carried out with satisfactory results on the final bulk vaccine, these tests may be omitted on the final lot.

IDENTIFICATION

The vaccine is shown to contain rabies virus antigen by a suitable immunochemical method (2.7.1) using specific antibodies, preferably monoclonal; alternatively, the assay serves also to identify the vaccine.

TESTS

Inactivation. Inoculate a quantity equivalent to not less than 25 human doses of vaccine into cell cultures of the same type as those used for production of the vaccine. Make a passage after 7 days. Maintain the cultures for a further 14 days and then examine the cell cultures for rabies virus using an immunofluorescence test. No rabies virus is detected.

Bovine serum albumin. Not more than 50 ng per single human dose, determined by a suitable immunochemical method (2.7.1).

Sterility (2.6.1). The vaccine complies with the test for sterility.

Bacterial endotoxins (2.6.14): less than 25 IU per single human dose.

Pyrogens (2.6.8). The vaccine complies with the test for pyrogens. Unless otherwise justified and authorised, inject into each rabbit a single human dose of the vaccine diluted to ten times its volume.

Water (2.5.12). Not more than 3.0 per cent, determined by the semi-micro determination of water.

ASSAY

The potency of rabies vaccine is determined by comparing the dose necessary to protect mice against the effects of a lethal dose of rabies virus, administered intracerebrally, with the quantity of a reference preparation of rabies vaccine necessary to provide the same protection. For this comparison a reference preparation of rabies vaccine, calibrated in International Units, and a suitable preparation of rabies virus for use as the challenge preparation are necessary.

The International Unit is the activity contained in a stated quantity of the International Standard. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The test described below uses a parallel-line model with at least three points for the vaccine to be examined and the reference preparation. Once the analyst has experience with the method for a given vaccine, it is possible to carry out a simplified test using a single dilution of the vaccine to be examined. Such a test enables the analyst to determine that the vaccine has a potency significantly higher than the required minimum but will not give full information on the validity of each individual potency determination. The use of a single dilution allows a considerable reduction in the number of animals required for the test and must be considered by each laboratory in accordance with the

provisions of the European Convention for the Protection of Vertebrate Animals used for Experimental and other Scientific Purposes.

01/2005:0162
corrected

Selection and distribution of the test animals. Use in the test healthy female mice about 4 weeks old, each weighing 11 g to 15 g, and from the same stock. Distribute the mice into six groups of a size suitable to meet the requirements for validity of the test and, for titration of the challenge suspension, four groups of five.

Preparation of the challenge suspension. Inoculate mice intracerebrally with the CVS strain of rabies virus and when the mice show signs of rabies, but before they die, sacrifice them, remove the brains and prepare a homogenate of the brain tissue in a suitable diluent. Separate gross particulate matter by centrifugation and use the supernatant liquid as the challenge suspension. Distribute the suspension in small volumes in ampoules, seal and store at a temperature below -60°C . Thaw one ampoule of the suspension and make serial dilutions in a suitable diluent. Allocate each dilution to a group of five mice and inject intracerebrally into each mouse 0.03 ml of the dilution allocated to its group. Observe the mice for 14 days. Calculate the LD_{50} of the undiluted suspension using the number in each group that, between the fifth and fourteenth days, die or develop signs of rabies.

Determination of potency of the vaccine to be examined. Prepare three fivefold serial dilutions of the vaccine to be examined and three fivefold serial dilutions of the reference preparation. Prepare the dilutions such that the most concentrated suspensions may be expected to protect more than 50 per cent of the animals to which they are administered and the least concentrated suspensions may be expected to protect less than 50 per cent of the animals to which they are administered. Allocate the six dilutions one to each of the six groups of mice and inject intraperitoneally into each mouse 0.5 ml of the dilution allocated to its group. After 7 days, prepare three identical dilutions of the vaccine to be examined and of the reference preparation and repeat the injections. Seven days after the second injection, prepare a suspension of the challenge virus such that, on the basis of the preliminary titration, 0.03 ml contains about 50 LD_{50} . Inject intracerebrally into each vaccinated mouse 0.03 ml of this suspension. Prepare three suitable serial dilutions of the challenge suspension. Allocate the challenge suspension and the three dilutions one to each of the four groups of five control mice and inject intracerebrally into each mouse 0.03 ml of the suspension or one of the dilutions allocated to its group. Observe the animals in each group for 14 days and record the number in each group that die or show signs of rabies in the period 5 days to 14 days after challenge.

The test is not valid unless: for both the vaccine to be examined and the reference preparation the 50 per cent protective dose lies between the largest and smallest doses given to the mice; the titration of the challenge suspension shows that 0.03 ml of the suspension contained not less than 10 LD_{50} ; the statistical analysis shows a significant slope and no significant deviations from linearity or parallelism of the dose-response lines; the confidence limits ($P = 0.95$) are not less than 25 per cent and not more than 400 per cent of the estimated potency.

The vaccine complies with the test if the estimated potency is not less than 2.5 IU per human dose.

LABELLING

The label states the biological origin of the cells used for the preparation of the vaccine.

RUBELLA VACCINE (LIVE)

Vaccinum rubellae vivum

DEFINITION

Rubella vaccine (live) is a freeze-dried preparation of a suitable attenuated strain of rubella virus. The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The production of vaccine is based on a virus seed-lot system and a cell-bank system. The production method shall have been shown to yield consistently live rubella vaccines of adequate immunogenicity and safety in man. Unless otherwise justified and authorised, the virus in the final vaccine shall have undergone no more passages from the master seed lot than were used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in human diploid cells (5.2.3).

SEED LOT

The strain of rubella virus used shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation. To avoid the unnecessary use of monkeys in the test for neurovirulence, virus seed lots are prepared in large quantities and stored at temperatures below -20°C if freeze-dried, or below -60°C if not freeze-dried.

Only a seed lot that complies with the following requirements may be used for virus propagation.

Identification. The master and working seed lots are identified as rubella virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration of the master and working seed lots is determined to ensure consistency of production.

Extraneous agents (2.6.16). The working seed lot complies with the requirements for seed lots.

Neurovirulence (2.6.18). The working seed lot complies with the test for neurovirulence of live virus vaccines. *Macaca* and *Cercopithecus* monkeys are suitable for the test.

PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Suitable animal (but not human) serum may be used in the growth medium, but the final medium for maintaining cell growth during virus multiplication does not contain animal serum. Serum and trypsin used in the preparation of cell suspensions and culture media are shown to be free from extraneous agents. The cell culture medium may contain a pH indicator such as phenol red and suitable antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during production. Not less than 500 ml of the production cell cultures is set aside as uninfected cell cultures (control cells). The temperature of incubation is controlled during the growth of the virus. The virus suspension is harvested,

on one or more occasions, within 28 days of inoculation. Multiple harvests from the same production cell culture may be pooled and considered as a single harvest.

Only a single harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. The single harvest contains virus that is identified as rubella virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration in the single harvest is determined as prescribed under Assay to monitor consistency of production and to determine the dilution to be used for the final bulk vaccine.

Extraneous agents (2.6.16). The single harvest complies with the tests for extraneous agents.

Control cells. The control cells comply with a test for identification and with the tests for extraneous agents (2.6.16).

FINAL BULK VACCINE

Single harvests that comply with the above tests are pooled and clarified to remove cells. A suitable stabiliser may be added and the pooled harvests diluted as appropriate.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Bacterial and fungal contamination. The final bulk vaccine complies with the test for sterility (2.6.1), carried out using 10 ml for each medium.

FINAL LOT

A minimum virus concentration for release of the product is established such as to ensure, in the light of stability data, that the minimum concentration stated on the label will be present at the end of the period of validity.

Only a final lot that complies with the requirements for minimum virus concentration for release, with the following requirement for thermal stability and with each of the requirements given below under Identification and Tests may be released for use. Provided that the test for bovine serum albumin has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Thermal stability. Maintain samples of the final lot of freeze-dried vaccine in the dry state at 37 °C for 7 days. Determine the virus concentration as described under Assay in parallel for the heated vaccine and for unheated vaccine stored at 5 ± 3 °C. The virus concentration of the heated vaccine is not more than 1.0 log₁₀ lower than that of the unheated vaccine.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with specific rubella antibodies, it is no longer able to infect susceptible cell cultures.

TESTS

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (2.6.1).

Bovine serum albumin. Not more than 50 ng per single human dose, determined by a suitable immunochemical method (2.7.1).

Water (2.5.12). Not more than 3.0 per cent, determined by the semi-micro determination of water.

ASSAY

Titrate the vaccine for infective virus at least in triplicate, using at least 5 cell cultures for each 0.5 log₁₀ dilution step or by a method of equal precision. Use an appropriate virus

reference preparation to validate each assay. The estimated virus concentration is not less than that stated on the label; the minimum virus concentration stated on the label is not less than 1 × 10³ CCID₅₀ per human dose. The assay is not valid if the confidence interval ($P = 0.95$) of the logarithm of the virus concentration is greater than ± 0.3.

Rubella vaccine (live) BRP is suitable for use as a reference preparation.

LABELLING

The label states:

- the strain of virus used for the preparation of the vaccine,
- the type and origin of the cells used for the preparation of the vaccine,
- the minimum virus concentration,
- that contact with disinfectants is to be avoided,
- the time within which the vaccine must be used after reconstitution,
- that the vaccine must not be given to a pregnant woman and that a woman must not become pregnant within 2 months after having the vaccine.

01/2005:0452

TETANUS VACCINE (ADSORBED)

Vaccinum tetani adsorbatum

DEFINITION

Tetanus vaccine (adsorbed) is a preparation of tetanus formol toxoid with a mineral adsorbent. The formol toxoid is prepared from the toxin produced by the growth of *Clostridium tetani*.

PRODUCTION

GENERAL PROVISIONS

Specific toxicity. The production method is validated to demonstrate that the product, if tested, would comply with the following test: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 21 days of the injection any of the animals shows signs of or dies from tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

BULK PURIFIED TOXOID

For the production of tetanus toxin, from which toxoid is prepared, seed cultures are managed in a defined seed-lot system in which toxinogenicity is conserved and, where necessary, restored by deliberate reselection. A highly toxinogenic strain of *Clostridium tetani* with known origin and history is grown in a suitable liquid medium. At the end of cultivation, the purity of each culture is tested and contaminated cultures are discarded. Toxin-containing culture medium is collected aseptically. The toxin content (Lf per millilitre) is checked to monitor consistency of production. Single harvests may be pooled to prepare the bulk purified toxoid. The toxin is purified to remove components likely to cause adverse reactions in humans. The purified toxin is detoxified with formaldehyde by a method that avoids destruction of the immunogenic potency of the toxoid and reversion of toxoid to toxin, particularly on exposure to heat. Alternatively, purification may be carried out after detoxification.

Only bulk purified toxoid that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

Absence of toxin and irreversibility of toxoid. Using the same buffer solution as for the final vaccine, without adsorbent, prepare a solution of bulk purified toxoid at the same concentration as in the final vaccine. Divide the dilution into 2 equal parts. Keep one of them at 5 ± 3 °C and the other at 37 °C for 6 weeks. Test both dilutions as described below. Use 15 guinea-pigs, each weighing 250-350 g and that have not previously been treated with any material that will interfere with the test. Inject subcutaneously into each of 5 guinea-pigs 5 ml of the dilution incubated at 5 ± 3 °C. Inject subcutaneously into each of 5 other guinea-pigs 5 ml of the dilution incubated at 37 °C. Inject subcutaneously into each of 5 guinea-pigs at least 500 Lf of the non-incubated bulk purified toxoid in a volume of 1 ml. The bulk purified toxoid complies with the test if during the 21 days following the injection no animal shows signs of or dies from tetanus. If more than 1 animal dies from non-specific causes, repeat the test; if more than 1 animal dies in the second test, the toxoid does not comply with the test.

Antigenic purity. Not less than 1000 Lf per milligram of protein nitrogen.

FINAL BULK VACCINE

The final bulk vaccine is prepared by adsorption of a suitable quantity of bulk purified toxoid onto a mineral carrier such as hydrated aluminium phosphate or aluminium hydroxide; the resulting mixture is approximately isotonic with blood. Suitable antimicrobial preservatives may be added. Certain antimicrobial preservatives, particularly those of the phenolic type, adversely affect the antigenic activity and must not be used.

Only final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (2.6.1). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the test for antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the free formaldehyde content has been determined on the bulk purified toxoid or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

IDENTIFICATION

Tetanus toxoid is identified by a suitable immunochemical method (2.7.1). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l

solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable tetanus antitoxin, giving a precipitate.

TESTS

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (2.6.1). The vaccine complies with the test for sterility.

ASSAY

Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (2.7.8).

The lower confidence limit ($P = 0.95$) of the estimated potency is not less than 40 IU per single human dose.

LABELLING

The label states:

- the minimum number of International Units per single human dose,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2005:1375

TICK-BORNE ENCEPHALITIS VACCINE (INACTIVATED)

Vaccinum encephalitis ixodibus advectae inactivatum

DEFINITION

Tick-borne encephalitis vaccine (inactivated) is a liquid preparation of a suitable strain of tick-borne encephalitis virus grown in cultures of chick-embryo cells or other suitable cell cultures and inactivated by a suitable, validated method.

PRODUCTION

Production of the vaccine is based on a virus seed-lot system. The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man. Unless otherwise justified and authorised, the virus in the final vaccine shall not have undergone more passages from the master seed lot than the virus in the vaccine used in clinical trials.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in chick embryo cells prepared from eggs derived from a chicken flock free from specified pathogens (5.2.2) or in other suitable cell cultures (5.2.3).

SEED LOTS

The strain of virus used is identified by historical records that include information on the origin of the strain and its subsequent manipulation. Virus seed lots are stored at or below $-60\text{ }^{\circ}\text{C}$.

Only a seed lot that complies with the following requirements may be used for virus propagation.

Identification. Each seed lot is identified as containing the vaccine strain of tick-borne encephalitis virus by a suitable immunochemical method (2.7.1), preferably using monoclonal antibodies.

Virus concentration. The virus concentration of each seed lot is determined by titration in suitable cell cultures to monitor consistency of production.

Extraneous agents (2.6.16). Each seed lot complies with the requirements for extraneous agents in viral vaccines for human use; the tests in cell cultures are carried out in human and simian cells only. For neutralisation of the vaccine virus, the use of monoclonal antibodies is preferable.

VIRUS PROPAGATION AND HARVEST

All processing of the cell cultures is performed under aseptic conditions in an area where no other cells are being handled. Serum and trypsin used in the preparation of cell suspensions and media used must be shown to be free from extraneous agents. The cell culture media may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration. At least 500 ml of the cell cultures employed for vaccine production is set aside as uninfected cell cultures (control cells).

Only a single harvest that complies with the following requirements may be used in the preparation of the inactivated harvest.

Identification. The single harvest is shown to contain tick-borne encephalitis virus by a suitable immunochemical method (2.7.1), preferably using monoclonal antibodies, or by virus neutralisation in cell cultures.

Bacterial and fungal contamination (2.6.1). The single harvest complies with the test for sterility, carried out using 10 ml for each medium.

Mycoplasmas (2.6.7). The single harvest complies with the test for mycoplasmas carried out using 1 ml for each medium.

Control cells. The control cells comply with the tests for extraneous agents (2.6.16). If the vaccine is produced using a cell-bank system, the control cells comply with a test for identification.

Virus concentration. Determine the virus concentration by titration in suitable cell cultures to monitor consistency of production.

INACTIVATION

To avoid interference, viral aggregates are removed by filtration immediately before the inactivation process. The virus suspension is inactivated by a validated method; the method shall have been shown to be consistently capable of inactivating tick-borne encephalitis virus without destroying the antigenic and immunogenic activity; as part of the validation studies, an inactivation curve is plotted representing residual live virus concentration measured on not fewer than three occasions. If formaldehyde is used for inactivation, the presence of an excess of free formaldehyde is verified at the end of the inactivation process.

Only an inactivated harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Residual infective virus. Inoculate a quantity of the inactivated harvest equivalent to not less than ten human doses of vaccine in the final lot into primary chicken fibroblast cell cultures, or other cells shown to be at least as sensitive to tick-borne encephalitis virus, with not less than 3 cm^2 of cell sheet per millilitre of inoculum. Incubate at $37 \pm 1\text{ }^{\circ}\text{C}$ for 14 days. No cytopathic effect is detected at the end of the incubation period. Collect the culture fluid and inoculate 0.03 ml intracerebrally into each of not fewer than ten mice about 4 weeks old. Observe the mice for 14 days. They show no evidence of tick-borne encephalitis virus infection.

PURIFICATION

Several inactivated single harvests may be pooled before concentration and purification by suitable methods, preferably by continuous-flow, sucrose density-gradient centrifugation.

Only a purified, inactivated harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Sterility (2.6.1). The purified, inactivated harvest complies with the test for sterility carried out using 10 ml for each medium.

Specific activity. Determine the antigen content of the purified, inactivated harvest by a suitable immunochemical method (2.7.1). Determine the total protein content by a suitable method. The specific activity, calculated as the antigen content per unit mass of protein, is within the limits approved for the specific product.

FINAL BULK VACCINE

The final bulk vaccine is prepared from one or more purified, inactivated harvests.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Sterility (2.6.1). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the tests for free formaldehyde, bovine serum albumin (where applicable) and pyrogens and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

IDENTIFICATION

The vaccine is shown to contain tick-borne encephalitis virus antigen by a suitable immunochemical method (2.7.1) using specific antibodies or by the mouse immunogenicity test described under Assay.

TESTS

Aluminium (2.5.13): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (2.4.18): maximum of 0.1 g/l.

Bovine serum albumin. If bovine serum albumin has been used during production, the vaccine contains not more than 50 ng per single human dose, determined by a suitable immunochemical method (2.7.1).

Sterility (2.6.1). The vaccine complies with the test for sterility.

Pyrogens (2.6.8). The vaccine complies with the test for pyrogens. Inject into each rabbit, per kilogram of body mass, one dose of vaccine.

ASSAY

The potency is determined by comparing the dose necessary to protect a given proportion of mice against the effects of a lethal dose of tick-borne encephalitis virus, administered intraperitoneally, with the quantity of a reference preparation of tick-borne encephalitis vaccine necessary to provide the same protection. For this comparison an approved reference preparation and a suitable preparation of tick-borne encephalitis virus from an approved strain for use as the challenge preparation are necessary.

The following is cited as an example of a method that has been found suitable for a given vaccine.

Selection and distribution of test animals. Use healthy mice weighing 11 g to 17 g and derived from the same stock. Distribute the mice into not fewer than six groups of a suitable size to meet the requirements for validity of the test; for titration of the challenge suspension, use not fewer than four groups of ten mice. Use mice of the same sex or distribute males and females equally between groups.

Determination of potency of the vaccine. Prepare not fewer than three suitable dilutions of the vaccine to be examined and of the reference preparation; in order to comply with validity criteria four to five dilutions will usually be necessary. Prepare dilutions such that the most concentrated suspension is expected to protect more than 50 per cent of the animals and the least concentrated suspension less than 50 per cent. Allocate each dilution to a different group of mice and inject subcutaneously into each mouse 0.2 ml of the dilution allocated to its group. 7 days later make a second injection using the same dilution scale. 14 days after the second injection prepare a suspension of the challenge virus containing not less than 100 LD₅₀ in 0.2 ml. Inject 0.2 ml of this virus suspension intraperitoneally into each vaccinated mouse. To verify the challenge dose, prepare a series of not fewer than three dilutions of the challenge virus suspension at not greater than one-hundredfold intervals. Allocate the challenge suspension and the four dilutions, one to each of the five groups of ten mice, and inject intraperitoneally into each mouse 0.2 ml of the challenge suspension or the dilution allocated to its group. Observe the animals for 21 days after the challenge and record the number of mice that die in the period between 7 days and 21 days after the challenge.

Calculations. Calculate the results by the usual statistical methods for an assay with quantal responses (for example, 5.3.).

Validity criteria. The test is not valid unless:

- the concentration of the challenge virus is not less than 100 LD₅₀,
- for both the vaccine to be examined and the reference preparation the 50 per cent protective dose (PD₅₀) lies between the largest and smallest doses given to the mice,
- the statistical analysis shows a significant slope and no significant deviation from linearity and parallelism of the dose-response lines,
- the confidence limits ($P = 0.95$) are not less than 33 per cent and not more than 300 per cent of the estimated potency.

Potency requirement. Include all valid tests to estimate the mean potency and the confidence limits ($P = 0.95$) for the mean potency; compute weighted means with the inverse of the squared standard error as weights. The vaccine complies with the test if the estimated potency is not less than that approved by the competent authority, based on data from clinical efficacy trials.

LABELLING

The label states:

- the strain of virus used in preparation,
- the type of cells used for production of the vaccine.

01/2005:1160

TYPHOID POLYSACCHARIDE VACCINE

Vaccinum febris typhoidis polysaccharidicum

DEFINITION

Typhoid polysaccharide vaccine is a preparation of purified Vi capsular polysaccharide obtained from *Salmonella typhi* Ty 2 strain or some other suitable strain that has the capacity to produce Vi polysaccharide.

Capsular Vi polysaccharide consists of partly 3-*O*-acetylated repeated units of 2-acetyl-amino-2-deoxy-D-galactopyranuronic acid with α -(1→4) linkages.

PRODUCTION

The production of Vi polysaccharide is based on a seed-lot system. The method of production shall have been shown to yield consistently typhoid polysaccharide vaccines of adequate immunogenicity and safety in man.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

BACTERIAL SEED LOTS

The strain of *S. typhi* used for the master seed lot shall be identified by historical records that include information on its origin and by its biochemical and serological characteristics. Cultures from the working seed lot shall have the same characteristics as the strain that was used to prepare the master seed lot.

Only a strain that has the following characteristics may be used in the preparation of the vaccine: (a) stained smears from a culture are typical of enterobacteria; (b) the culture utilises glucose without production of gas; (c) colonies on agar are oxidase-negative; (d) a suspension of the culture agglutinates specifically with a suitable Vi antiserum or colonies form haloes on an agar plate containing a suitable Vi antiserum.

Purity of bacterial strain used for the seed lot is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

CULTURE AND HARVEST

The working seed lot is cultured on a solid medium, which may contain blood-group substances, or a liquid medium; the inoculum obtained is transferred to a liquid medium which is used to inoculate the final medium. The liquid medium used and the final medium are semi-synthetic, free from substances that are precipitated by cetrimonium bromide and do not contain blood-group substances or high-molecular-mass polysaccharides, unless it has been demonstrated that they are removed by the purification process.

The bacterial purity of the culture is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

The culture is then inactivated at the beginning of the stationary phase by the addition of formaldehyde. Bacterial cells are eliminated by centrifugation; the polysaccharide is precipitated from the culture medium by addition of hexadecyltrimethylammonium bromide (cetrimonium bromide). The precipitate is harvested and may be stored at -20°C before purification.

PURIFIED VI POLYSACCHARIDE

The polysaccharide is purified, after dissociation of the polysaccharide/cetrimonium bromide complex, using suitable procedures to eliminate successively nucleic acids, proteins and lipopolysaccharides. The polysaccharide is precipitated as the calcium salt in the presence of ethanol and dried at $2-8^{\circ}\text{C}$; the powder obtained constitutes the purified Vi polysaccharide. The loss on drying is determined by thermogravimetry (2.2.34) and is used to calculate the results of the chemical tests shown below with reference to the dried substance.

Only a purified Vi polysaccharide that complies with the following requirements may be used in the preparation of the final bulk.

Protein (2.5.16): maximum 10 mg per gram of polysaccharide, calculated with reference to the dried substance.

Nucleic acids (2.5.17): maximum 20 mg per gram of polysaccharide, calculated with reference to the dried substance.

O-Acetyl groups (2.5.19): minimum 2 mmol per gram of polysaccharide, calculated with reference to the dried substance.

Molecular size. Examine by size-exclusion chromatography (2.2.30) using *cross-linked agarose for chromatography R*. Use a column 0.9 m long and 16 mm in internal diameter equilibrated with a solvent having an ionic strength of 0.2 mol/kg and a pH of 7.0-7.5. Apply about 5 mg of polysaccharide in a volume of 1 ml to the column and elute at about 20 ml/h. Collect fractions of about 2.5 ml. Determine the point corresponding to $K_0 = 0.25$ and make 2 pools consisting of fractions eluted before and after this point. Determine O-acetyl groups on the 2 pools (2.5.19). Not less than 50 per cent of the polysaccharide is found in the pool containing fractions eluted before $K_0 = 0.25$.

Identification. Carry out an identification test using a suitable immunochemical method (2.7.1).

Bacterial endotoxins. The content of bacterial endotoxins determined by a suitable method (2.6.14) is within the limits approved for the specific product.

FINAL BULK VACCINE

One or more batches of purified Vi polysaccharide are dissolved in a suitable solvent, which may contain an antimicrobial preservative, so that the volume corresponding to 1 dose contains 25 µg of polysaccharide and the solution is isotonic with blood (250 mosmol/kg to 350 mosmol/kg).

Only a final bulk vaccine that complies with the following tests may be used in the preparation of the final lot.

Sterility (2.6.1). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable physicochemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile tamper-proof containers that are then closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements prescribed below under Identification, Tests and Assay and with the requirement for bacterial endotoxins may be released for use. Provided the tests for free formaldehyde and antimicrobial preservative have been carried out on the final bulk vaccine, they may be omitted on the final lot.

Bacterial endotoxins. The content of bacterial endotoxins determined by a suitable method (2.6.14) is within the limit approved for the specific product.

CHARACTERS

Clear colourless liquid, free from visible particles.

IDENTIFICATION

Carry out an identification test using a suitable immunochemical method (2.7.1).

TESTS

pH (2.2.3): 6.5 to 7.5.

O-Acetyl groups: 0.085 (± 25 per cent) µmol per dose (25 µg of polysaccharide).

Test solution. Place 3 ml of the vaccine in each of 3 tubes (2 reaction solutions and 1 correction solution).

Reference solutions. Dissolve 0.150 g of *acetylcholine chloride R* in 10 ml of *water R* (stock solution containing 15 g/l of acetylcholine chloride). Immediately before use, dilute 0.5 ml of the stock solution to 50 ml with *water R* (working dilution containing 150 µg/ml of acetylcholine chloride). In 10 tubes, place in duplicate (reaction and correction solutions) 0.1 ml, 0.2 ml, 0.5 ml, 1.0 ml and 1.5 ml of the working dilution.

Prepare a blank using 3 ml of *water R*.

Make up the volume in each tube to 3 ml with *water R*. Add 0.5 ml of a mixture of 1 volume of *water R* and 2 volumes of *dilute hydrochloric acid R* to each of the correction tubes and to the blank. Add 1.0 ml of *alkaline hydroxylamine solution R* to each tube. Allow the reaction to proceed for exactly 2 min and add 0.5 ml of a mixture of 1 volume of *water R* and 2 volumes of *dilute hydrochloric acid R* to each of the reaction tubes. Add 0.5 ml of a 200 g/l solution of *ferric chloride R* in 0.2 M *hydrochloric acid* to each tube, stopper the tubes and shake vigorously to remove bubbles.

Measure the absorbance (2.2.25) of each solution at 540 nm using the blank as the compensation liquid. For each reaction solution, subtract the absorbance of the corresponding correction solution. Draw a calibration curve from the corrected absorbances for the 5 reference solutions and the corresponding content of acetylcholine chloride and read from the curve the content of acetylcholine chloride in the test solution for each volume tested. Calculate the mean of the 2 values.

1 mole of acetylcholine chloride (181.7 g) is equivalent to 1 mole of O-acetyl (43.05 g).

Free formaldehyde (2.4.18): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable physicochemical method. The content is not less than the minimum amount shown to be effective and not more than 115 per cent of the content stated on the label. If phenol has been used in the preparation, the content is not more than 2.5 g/l (2.5.15).

Sterility (2.6.1). The vaccine complies with the test for sterility.

ASSAY

Determine Vi polysaccharide by a suitable immunochemical method (2.7.1), using a reference purified polysaccharide. The estimated amount of polysaccharide per dose is 80 per cent to 120 per cent of the content stated on the label. The confidence limits ($P = 0.95$) of the estimated amount of polysaccharide are not less than 80 per cent and not more than 120 per cent.

LABELLING

The label states:

- the number of micrograms of polysaccharide per human dose (25 µg),
- the total quantity of polysaccharide in the container.

01/2005:0156

TYPHOID VACCINE

Vaccinum febris typhoidi

DEFINITION

Typhoid vaccine is a sterile suspension of inactivated *Salmonella typhi* containing not less than 5×10^8 and not more than 1×10^9 bacteria (*S. typhi*) per human dose. The human dose does not exceed 1.0 ml.

PRODUCTION

The vaccine is prepared using a seed-lot system from a suitable strain, such as Ty 2⁽⁵⁾, of *S. typhi*. The final vaccine represents not more than 3 subcultures from the strain on which were made the laboratory and clinical tests that showed it to be suitable. The bacteria are inactivated by acetone, by formaldehyde, by phenol or by heating or by a combination of the last 2 methods.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9) modified as follows: inject 0.5 ml of the vaccine into each mouse and 1.0 ml into each guinea pig.

IDENTIFICATION

It is identified by specific agglutination.

TESTS

Phenol (2.5.15). If phenol has been used in the preparation, the concentration is not more than 5 g/l.

Antigenic power. When injected into susceptible laboratory animals, it elicits anti-O, anti-H and, to a lesser extent, anti-Vi agglutinins.

Sterility (2.6.1). It complies with the test for sterility.

LABELLING

The label states:

- the method used to inactivate the bacteria,
- the number of bacteria per human dose.

01/2005:0157

TYPHOID VACCINE, FREEZE-DRIED

Vaccinum febris typhoidi cryodesiccatum

DEFINITION

Freeze-dried typhoid vaccine is a freeze-dried preparation of inactivated *Salmonella typhi*. The vaccine is reconstituted as stated on the label to give a uniform suspension containing not less than 5×10^8 and not more than 1×10^9 bacteria (*S. typhi*) per human dose. The human dose does not exceed 1.0 ml of the reconstituted vaccine.

PRODUCTION

The vaccine is prepared using a seed-lot system from a suitable strain, such as Ty 2⁽⁶⁾, of *S. typhi*. The final vaccine represents not more than 3 subcultures from the strain on which were made the laboratory and clinical tests that showed it to be suitable. The bacteria are inactivated either by acetone or by formaldehyde or by heat. Phenol is not used in the preparation. The vaccine is distributed into sterile containers and freeze-dried to a moisture content favourable to the stability of the vaccine. The containers are then closed so as to exclude contamination.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9) modified as follows: inject 0.5 ml of the vaccine into each mouse and 1.0 ml into each guinea pig.

IDENTIFICATION

The vaccine reconstituted as stated on the label is identified by specific agglutination.

TESTS

Phenol (2.5.15). If phenol has been used in the preparation, the concentration is not more than 5 g/l.

Antigenic power. When injected into susceptible laboratory animals, the reconstituted vaccine elicits anti-O, anti-H and, to a lesser extent, anti-Vi agglutinins.

Sterility (2.6.1). The reconstituted vaccine complies with the test for sterility.

LABELLING

The label states:

- the method used to inactivate the bacteria,
- the number of bacteria per human dose,
- that the vaccine should be used within 8 h of reconstitution.

(5) This strain is issued by the World Health Organisation Collaborating Centre for Reference and Research on Bacterial Vaccines, Human Serum and Vaccine Institute, Szallas Utea 5, H-1107, Budapest, Hungary.

01/2005:1055

TYPHOID VACCINE (LIVE, ORAL, STRAIN Ty 21a)

Vaccinum febris typhoidis vivum perorale (stirpe Ty 21a)

DEFINITION

Typhoid vaccine (live, oral, strain Ty 21a) is a freeze-dried preparation of live *Salmonella typhi* strain Ty 21a grown in a suitable medium. When presented in capsules, the vaccine complies with the monograph on *Capsules* (0016).

PRODUCTION

CHOICE OF VACCINE STRAIN

The main characteristic of the strain is the defect of the enzyme uridine diphosphate-galactose-4-epimerase. The activities of galactopermease, galactokinase and galactose-1-phosphate uridyl-transferase are reduced by 50 per cent to 90 per cent. Whatever the growth conditions, the strain does not contain Vi antigen. The strain agglutinates to anti-O:9 antiserum only if grown in medium containing galactose. It contains the flagellar H:d antigen and does not produce hydrogen sulphide on Kligler iron agar. The strain is nonvirulent for mice. Cells of strain Ty 21a lyse if grown in the presence of 1 per cent of galactose.

BACTERIAL SEED LOTS

The vaccine is prepared using a seed-lot system. The working seed lots represent not more than one subculture from the master seed lot. The final vaccine represents not more than four subcultures from the original vaccine on which were made the laboratory and clinical tests showing the strain to be suitable.

Only a master seed lot that complies with the following requirements may be used in the preparation of working seed lots.

Galactose metabolism. In a spectrophotometric assay, no activity of the enzyme uridine diphosphate-galactose-4-epimerase is found in the cytoplasm of strain Ty 21a compared to strain Ty 2.

Biosynthesis of lipopolysaccharide. Lipopolysaccharides are extracted by the hot-phenol method and examined by size-exclusion chromatography. Strain Ty 21a grown in medium free of galactose shows only the rough (R) type of lipopolysaccharide.

Serological characteristics. Strain Ty 21a grown in a synthetic medium without galactose does not agglutinate to specific anti-O:9 antiserum. Whatever the growth conditions, strain Ty 21a does not agglutinate to Vi antiserum. Strain Ty 21a agglutinates to H:d flagellar antiserum.

Biochemical markers. Strain Ty 21a does not produce hydrogen sulphide on Kligler iron agar. This property serves to distinguish Ty 21a from other galactose-epimerase-negative *S. typhi* strains.

Cell growth. Strain Ty 21a cells lyse when grown in the presence of 1 per cent of galactose.

BACTERIAL PROPAGATION AND HARVEST

The bacteria from the working seed lot are multiplied in a preculture, subcultured once and are then grown in a suitable medium containing 0.001 per cent of galactose at 30 °C for 13 h to 15 h. The bacteria are harvested. The harvest must be free from contaminating micro-organisms.

Only a single harvest that complies with the following requirements may be used for the preparation of the freeze-dried harvest.

pH. The pH of the culture is 6.8 to 7.5.

Optical density. The optical density of the culture, measured at 546 nm, is 6.5 to 11.0. Before carrying out the measurement, dilute the culture so that a reading in the range 0.1 to 0.5 is obtained and correct the reading to take account of the dilution.

Identification. Culture bacteria on an agar medium containing 1 per cent of galactose and bromothymol blue. Light blue, concave colonies, transparent due to lysis of cells, are formed. No yellow colonies (galactose-fermenting) are found.

FREEZE-DRIED HARVEST

The harvest is mixed with a suitable stabiliser and freeze-dried by a process that ensures the survival of at least 10 per cent of the bacteria and to a water content shown to be favourable to the stability of the vaccine. No antimicrobial preservative is added to the vaccine.

Only a freeze-dried harvest that complies with the following tests may be used for the preparation of the final bulk.

Identification. Culture bacteria are examined on an agar medium containing 1 per cent of galactose and bromothymol blue. Light blue, concave colonies, transparent due to lysis of cells, are formed. No yellow colonies (galactose-fermenting) are found.

Number of live bacteria. Not fewer than 1×10^{11} live *S. typhi* strain Ty 21a per gram.

Water (2.5.12): 1.5 per cent to 4.0 per cent, determined by the semi-micro determination of water.

FINAL BULK VACCINE

The final bulk vaccine is prepared by aseptically mixing one or more freeze-dried harvests with a suitable sterile excipient.

Only a final bulk that complies with the following requirement may be used in the preparation of the final lot.

Number of live bacteria. Not fewer than 40×10^9 live *S. typhi* strain Ty 21a per gram.

FINAL LOT

The final bulk vaccine is distributed under aseptic conditions into capsules with a gastro-resistant shell or into suitable containers.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Number of live bacteria may be released for use, except that in the determination of the number of live bacteria each dosage unit must contain not fewer than 4×10^9 live bacteria.

IDENTIFICATION

Culture bacteria from the vaccine to be examined on an agar medium containing 1 per cent of galactose and bromothymol blue. Light blue, concave colonies, transparent due to lysis of cells, are formed. No yellow colonies (galactose-fermenting) are found.

TESTS

Contaminating micro-organisms (2.6.12, 2.6.13). Carry out the test using suitable selective media. Determine the total viable count using the plate-count method. The number of contaminating micro-organisms per dosage unit is not greater than 10^2 bacteria and 20 fungi. No pathogenic bacterium, particularly *Escherichia coli*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and no salmonella other than strain Ty 21a are found.

Water (2.5.12): 1.5 per cent to 4.0 per cent, determined on the contents of the capsule or of the container by the semi-micro determination of water.

NUMBER OF LIVE BACTERIA

Carry out the test using not fewer than five dosage units. Homogenise the contents of the dosage units in a 9 g/l solution of *sodium chloride R* at 4 °C using a mixer in a cold room with sufficient glass beads to emerge from the liquid. Immediately after homogenisation prepare a suitable dilution of the suspension using cooled diluent and inoculate brain heart infusion agar; incubate at 36 ± 1 °C for 20 h to 36 h. The vaccine contains not fewer than 2×10^9 live *S. typhi* Ty 21a bacteria per dosage unit.

LABELLING

The label states:

- the minimum number of live bacteria per dosage unit,
- that the vaccine is for oral use only.

01/2005:0648

VARICELLA VACCINE (LIVE)

Vaccinum varicellae vivum

DEFINITION

Varicella vaccine (live) is a freeze-dried preparation of a suitable attenuated strain of *Herpesvirus varicellae*. The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The production of vaccine is based on a virus seed-lot system and a cell-bank system. The production method shall have been shown to yield consistently live varicella vaccines of adequate immunogenicity and safety in man. The virus in the final vaccine shall not have been passaged in cell cultures beyond the 38th passage from the original isolated virus.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in human diploid cells (5.2.3).

VIRUS SEED LOT

The strain of varicella virus shall be identified as being suitable by historical records which shall include information on the origin of the strain and its subsequent manipulation. The virus shall at no time have been passaged in continuous cell lines. Seed lots are prepared in the same kind of cells as those used for the production of the final vaccine.

To avoid the unnecessary use of monkeys in the test for neurovirulence, virus seed lots are prepared in large quantities and stored at temperatures below –20 °C, if freeze-dried, or below –60 °C, if not freeze-dried.

Only a virus seed lot that complies with the following requirements may be used for virus propagation.

Identification. The master and working seed lots are identified as varicella virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration of the master and working seed lots is determined as prescribed under Assay to monitor consistency of production.

Extraneous agents (2.6.16). The working seed lot complies with the requirements for seed lots for live virus vaccines; a sample of 50 ml is taken for the test in cell cultures.

Neurovirulence (2.6.18). The working seed lot complies with the test for neurovirulence of live virus vaccines.

VIRUS PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Approved animal (but not human) serum may be used in the media. Serum and trypsin used in the preparation of cell suspensions and media are shown to be free from extraneous agents. The cell culture medium may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during production. 5 per cent, but not less than 50 ml, of the cell cultures employed for vaccine production is set aside as uninfected cell cultures (control cells). The infected cells constituting a single harvest are washed, released from the support surface and pooled. The cell suspension is disrupted by sonication.

Only a virus harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. The virus harvest contains virus that is identified as varicella virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The concentration of infective virus in virus harvests is determined as prescribed under Assay to monitor consistency of production and to determine the dilution to be used for the final bulk vaccine.

Extraneous agents (2.6.16). Use 50 ml for the test in cell cultures.

Control cells. The control cells of the production cell culture from which the single harvest is derived comply with a test for identity and with the requirements for extraneous agents (2.6.16).

FINAL BULK VACCINE

Virus harvests that comply with the above tests are pooled and clarified to remove cells. A suitable stabiliser may be added and the pooled harvests diluted as appropriate.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1) using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers and freeze-dried to a moisture content shown to be favourable to the stability of the vaccine. The containers are then closed so as to prevent contamination and the introduction of moisture.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the test for bovine serum albumin has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with specific *Herpesvirus varicellae* antibodies, it is no longer able to infect susceptible cell cultures.

TESTS

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (2.6.1).

Bovine serum albumin. Not more than 0.5 µg per human dose, determined by a suitable immunochemical method (2.7.1).

Water (2.5.12). Not more than 3.0 per cent, determined by the semi-micro determination of water.

ASSAY

Titrate for infective virus, using at least 10 cell cultures for each fourfold dilution or by a technique of equal precision. Use a suitable virus reference preparation to validate each assay. The virus concentration is not less than the minimum stated on the label.

LABELLING

The label states:

- the strain of virus used for the preparation of the vaccine,
- the type and origin of the cells used for the preparation of the vaccine,
- that contact with disinfectants is to be avoided,
- the minimum virus concentration,
- that the vaccine is not to be administered to pregnant women,
- the time within which the vaccine must be used after reconstitution.

01/2005:0537

YELLOW FEVER VACCINE (LIVE)

Vaccinum febris flavae vivum

DEFINITION

Yellow fever vaccine (live) is a freeze-dried preparation of the 17D strain of yellow fever virus grown in fertilised hen eggs. The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid.

PRODUCTION

The production of vaccine is based on a virus seed-lot system. The production method shall have been shown to yield consistently yellow fever vaccine (live) of acceptable immunogenicity and safety for man.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (2.6.9) modified as follows for the test in guinea-pigs: inject ten human doses into each guinea-pig and observe for 21 days.

Reference preparation. In the test for neurotropism, a suitable batch of vaccine known to have satisfactory properties in man is used as the reference preparation.

SUBSTRATE FOR VIRUS PROPAGATION

Virus for the preparation of master and working seed lots and of all vaccine batches is grown in the tissues of chick embryos from a flock free from specified pathogens (5.2.2).

SEED LOTS

The 17D strain shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation. Virus seed lots are prepared in large quantities and stored at a temperature below –60 °C. Master and working seed lots shall not contain any human protein or added serum.

Unless otherwise justified and authorised, the virus in the final vaccine shall be between passage levels 204 and 239 from the original isolate of strain 17D. A working seed lot shall be only one passage from a master seed lot. A working seed lot shall be used without intervening passage as the

inoculum for infecting the tissues used in the production of a vaccine lot, so that no vaccine virus is more than one passage from a seed lot that has passed all the safety tests. Only a virus seed lot that complies with the following requirements may be used for virus propagation.

Identification. The master and working seed lots are identified as containing yellow fever virus by serum neutralisation in cell culture, using specific antibodies.

Extraneous agents (2.6.16). Each working seed lot complies with the following tests:

Bacterial and fungal sterility

Mycoplasmas

Mycobacteria

Avian viruses

Test in adult mice (intraperitoneal inoculation only)

Test in guinea-pigs

Tests in monkeys. Each master and working seed lot complies with the following tests in monkeys for viraemia (viscerotropism), immunogenicity and neurotropism.

The monkeys shall be *Macaca* sp. susceptible to yellow fever virus and shall have been shown to be non-immune to yellow fever at the time of injecting the seed virus. They shall be healthy and shall not have received previously intracerebral or intraspinal inoculation. Furthermore, they shall not have been inoculated by other routes with neurotropic viruses or with antigens related to yellow fever virus. Not fewer than ten monkeys are used for each test.

Use a test dose of 0.25 ml containing the equivalent of not less than 5000 mouse LD₅₀ and not more than 50 000 mouse LD₅₀, determined by a titration for infectious virus and using the established equivalence between virus concentration and mouse LD₅₀ (see under Assay). Inject the test dose into one frontal lobe of each monkey under anaesthesia and observe the monkeys for not less than 30 days.

Viraemia (Viscerotropism). Viscerotropism is indicated by the amount of virus present in serum. Take blood from each of the test monkeys on the second, fourth and sixth days after inoculation and prepare serum from each sample.

Prepare 1:10, 1:100 and 1:1000 dilutions from each serum and inoculate each dilution into a group of at least six cell culture vessels used for the determination of the virus concentration. The seed lot complies with the test if none of the sera contains more than the equivalent of 500 mouse LD₅₀ in 0.03 ml and at most one serum contains more than the equivalent of 100 mouse LD₅₀ in 0.03 ml.

Immunogenicity. Take blood from each monkey 30 days after the injection of the test dose and prepare serum from each sample. The seed lot complies with the test if at least 90 per cent of the test monkeys are shown to be immune, as determined by examining their sera in the test for neutralisation of yellow fever virus described below.

It has been shown that a low dilution of serum (for example, 1:10) may contain non-specific inhibitors that influence this test; such serum shall be treated to remove inhibitors. Mix dilutions of at least 1:10, 1:40 and 1:160 of serum from each monkey with an equal volume of 17D vaccine virus at a dilution that will yield an optimum number of plaques with the titration method used. Incubate the serum-virus mixtures in a water-bath at 37 °C for 1 h and then cool in iced water; add 0.2 ml of each serum-virus mixture to each of four cell-culture plates and proceed as for the determination of virus concentration. Inoculate similarly ten plates with the same amount of virus plus an equal volume of a 1:10 dilution of monkey serum known to contain no neutralising antibodies to yellow fever virus. At the end of the observation period, compare the mean number of plaques in the plates

receiving virus plus non-immune serum with the mean number of plaques in the plates receiving virus plus dilutions of each monkey serum. Not more than 10 per cent of the test monkeys have serum that fails to reduce the number of plaques by 50 per cent at the 1:10 dilution.

Neurotropism. Neurotropism is assessed from clinical evidence of encephalitis, from incidence of clinical manifestations and by evaluation of histological lesions, in comparison with ten monkeys injected with the reference preparation. The seed lot is not acceptable if either the onset and duration of the febrile reaction or the clinical signs of encephalitis and pathological findings are such as to indicate a change in the properties of the virus.

Clinical evaluation. - The monkeys are examined daily for 30 days by personnel familiar with clinical signs of encephalitis in primates (if necessary, the monkeys are removed from their cage and examined for signs of motor weakness or spasticity). The seed lot is not acceptable if in the monkeys injected with it the incidence of severe signs of encephalitis, such as paralysis or inability to stand when stimulated, or mortality is greater than for the reference vaccine. These and other signs of encephalitis, such as paresis, inco-ordination, lethargy, tremors or spasticity are assigned numerical values for the severity of symptoms by a grading method. Each day each monkey in the test is given a score based on the scale:

Grade 1 - rough coat, not eating,

Grade 2 - high-pitched voice, inactive, slow moving,

Grade 3 - shaky, tremors, unco-ordinated, limb weakness,

Grade 4 - inability to stand, limb paralysis or death (a dead monkey receives a daily score of 4 from the day of death until day 30).

A clinical score for a particular monkey is the average of its daily scores; the clinical score for the seed lot is the mean of the individual monkey scores. The seed lot is not acceptable if the mean of the clinical severity scores for the group of monkeys inoculated with it is significantly greater ($P = 0.95$) than the mean for the group of monkeys injected with the reference preparation. In addition, special consideration is given to any animal showing unusually severe signs when deciding on the acceptability of the seed lot.

Histological evaluation. - Five levels of the brain are examined including:

Block I - the corpus striatum at the level of the optic chiasma,
Block II - the thalamus at the level of the mamillary bodies,
Block III - the mesencephalon at the level of the superior colliculi,

Block IV - the pons and cerebellum at the level of the superior olives,

Block V - the medulla oblongata and cerebellum at the level of the mid-inferior olivary nuclei.

Cervical and lumbar enlargements of the spinal cord are each divided equally into six blocks; 15 µm sections are cut from the tissue blocks embedded in paraffin wax and stained with galloxyanin. Numerical scores are given to each hemisection of the cord and to structures in each hemisection of the brain as listed below. Lesions are scored as follows:

Grade 1. Minimal: 1 to 3 small focal inflammatory infiltrates. Degeneration or loss of a few neurons.

Grade 2. Moderate: 4 or more focal inflammatory infiltrates. Degeneration or loss of neurons affecting not more than one third of cells.

Grade 3. Severe: moderate focal or diffuse inflammatory infiltration. Degeneration or loss of up to two thirds of the neurons.

Grade 4. Overwhelming: variable but often severe inflammatory reaction. Degeneration or loss of more than 90 per cent of neurons.

It has been found that inoculation of yellow fever vaccine into the monkey brain causes histological lesions in different anatomical formations of the central nervous system with varying frequency and severity (I. S. Levenbook *et al.*, *Journal of Biological Standardization*, 1987, 15, 305-313). Based on these two indicators, the anatomical structures can be divided into target, spared and discriminator areas. Target areas are those which show more severe specific lesions in a majority of monkeys irrespective of the degree of neurovirulence of the seed lot. Spared areas are those which show only minimal specific lesions and in a minority of monkeys. Discriminator areas are those where there is a significant increase in the frequency of more severe specific lesions with seed lots having a higher degree of neurovirulence. Discriminator and target areas for *Macaca cynomolgus* and *Macaca rhesus* monkeys are shown in Table 0537-1.

Table 0537-1

Type of monkey	Discriminator areas	Target areas
<i>Macaca cynomolgus</i>	globus pallidus	substantia nigra
	putamen	
	anterior/median thalamic nucleus	
	lateral thalamic nucleus	
<i>Macaca rhesus</i>	caudate nucleus	substantia nigra
	globus pallidus	cervical enlargement
	putamen	lumbar enlargement
	anterior/median thalamic nucleus	
	lateral thalamic nucleus	
	cervical enlargement	
	lumbar enlargement	

Scores for discriminator and target areas are used for the final evaluation of the seed lot. The individual monkey score is calculated from the sum of individual target area scores in each hemisection divided by the number of areas examined. A separate score is calculated similarly for the discriminator areas.

Mean scores for the test group are calculated in two ways: (1) by dividing the sum of the individual monkey discriminator scores by the number of monkeys and (2) by dividing the sum of the individual monkey target and discriminator scores by the number of monkeys. These two mean scores are taken into account when deciding on the acceptability of the seed lot. The seed lot is not acceptable if either of the mean lesion scores is significantly greater ($P = 0.95$) than for the reference preparation.

PROPAGATION AND HARVEST

All processing of the fertilised eggs is done under aseptic conditions in an area where no other infectious agents or cells are handled at the same time. 2 per cent but not less than twenty and not more than fifty eggs are set aside as uninfected control eggs. After inoculation and incubation at a controlled temperature, only living and typical chick embryos are harvested. The age of the embryo at the time of virus harvest is reckoned from the initial introduction of the egg into the incubator and shall be not more than 12 days. After homogenisation and clarification by centrifugation, the extract of embryonic pulp is tested as described below

and kept at -70°C or colder until further processing. Virus harvests that comply with the prescribed tests may be pooled. No human protein is added to the virus suspension at any stage during production. If stabilisers are added, they shall have been shown to have no antigenic or sensitising properties for man.

Only a single harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. The single harvest contains virus that is identified as yellow fever virus by serum neutralisation in cell culture, using specific antibodies.

Extraneous agents (2.6.16). The single harvest complies with the tests for extraneous agents.

Control eggs (2.6.16). The control eggs comply with the tests for extraneous agents.

Virus concentration. In order to calculate the dilution for formulation of the final bulk, each single harvest is titrated as described under Assay.

FINAL BULK VACCINE

Single harvests that comply with the tests prescribed above are pooled and clarified again. A test for protein nitrogen content is carried out. A suitable stabiliser may be added and the pooled harvests diluted as appropriate.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Bacterial and fungal contamination. Carry out the test for sterility (2.6.1), using 10 ml for each medium.

Protein nitrogen content. The protein nitrogen content, before the addition of any stabiliser, is not more than 0.25 mg per human dose.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers and freeze-dried to a moisture content shown to be favourable to the stability of the vaccine. The containers are then closed so as to prevent contamination and the introduction of moisture.

Only a final lot that is satisfactory with respect to thermal stability and each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the test for ovalbumin has been performed with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Thermal stability. Maintain samples of the final lot of freeze-dried vaccine in the dry state at 37°C for 14 days. Determine the virus concentration as described under Assay in parallel for the heated vaccine and for unheated vaccine. The difference in the virus concentration between unheated and heated vaccine does not exceed $1.0 \log_{10}$ and the virus concentration of the heated vaccine is not less than the number of plaque-forming units (PFU) equivalent to 1×10^3 mouse LD_{50} per human dose.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with specific yellow fever virus antibodies, there is a significant reduction in its ability to infect susceptible cell cultures.

TESTS

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (2.6.1).

Ovalbumin. Not more than $5 \mu\text{g}$ of ovalbumin per human dose, determined by a suitable immunochemical method (2.7.1).

Bacterial endotoxins (2.6.14): less than 5 IU per human dose.

Water (2.5.12). Not more than 3.0 per cent, determined by the semi-micro determination of water.

ASSAY

Titrate for infective virus in cell cultures. Use an appropriate virus reference preparation to validate each assay.

The virus concentration is not less than the equivalent in PFU of 1×10^3 mouse LD_{50} per human dose. The relationship between mouse LD_{50} and PFU is established by each laboratory and approved by the competent authority. The method shown below, or another suitable technique, may be used to determine the mouse LD_{50} .

Suggested method for determination of the mouse LD_{50}

Mouse LD_{50} . The statistically calculated quantity of virus suspension that is expected to produce fatal specific encephalitis in 50 per cent of mice of a highly susceptible strain, 4 to 6 weeks of age, after intracerebral inoculation.

Appropriate serial dilutions of the reconstituted vaccine are made in diluent for yellow fever virus (a 7.5 g/l solution of bovine albumin R in phosphate-buffered saline pH 7.4 R, or any other diluent that has been shown to be equivalent for maintaining the infectivity of the virus).

Mice of a highly susceptible strain, 4 to 6 weeks of age, are injected intracerebrally under anaesthesia with 0.03 ml of the vaccine dilution. Groups of not fewer than six mice are used for each dilution; the series of dilutions is chosen so as to cover the range 0 to 100 per cent mortality of the mice. Injection of the mice is performed immediately after the dilutions have been made. The mice are observed for 21 days and all deaths are recorded. Only survivors and deaths caused by typical yellow fever infections are counted in the computations. Mice paralysed on the twenty-first day of observation are counted as survivors.

LABELLING

The label states:

- the strain of virus used in preparation,
- that the vaccine has been prepared in chick embryos,
- the minimum virus concentration,
- that contact with disinfectants is to be avoided,
- the period of time within which the vaccine is to be used after reconstitution.

01/2005:0441

ANTHRAX SPORE VACCINE (LIVE) FOR VETERINARY USE

Vaccinum anthracis vivum
ad usum veterinarium

DEFINITION

Anthrax spore live vaccine for veterinary use consists of a suspension of live spores of an attenuated, non-capsulated strain of *Bacillus anthracis*.

PRODUCTION

The strain used is either: not lethal to the guinea-pig or the mouse; or lethal to the guinea-pig but not to the rabbit; or lethal to some rabbits. *B. anthracis* is grown in an appropriate medium. At the end of growth the spores are suspended in a stabilising solution and counted. The vaccine may contain an adjuvant.

IDENTIFICATION

B. anthracis present in the vaccine is identified by means of morphological and serological tests, culture and biochemical tests.

TESTS

Safety. Carry out the test on one of the species of animals for which the vaccine is intended. If the vaccine is intended for several species, including the goat, carry out the test on goats. Administer subcutaneously or intradermally to each of 2 animals, of the minimum age recommended for vaccination and having no antibodies against *B. anthracis*, twice the dose stated on the label for the species used and observe the animals for 14 days. No abnormal systemic reaction is produced but a local reaction may occur at the site of injection. The severity of the local reaction may vary according to the strain of the spores and the adjuvants used in the preparation, but necrosis does not occur.

Spore count. The number of live spores determined by plate count is not less than 80 per cent of that stated on the label.

Bacterial and fungal contamination. Carry out the test by microscopic examination and by inoculation of suitable media. The vaccine does not contain contaminating bacteria or fungi.

POTENCY

For a strain of *B. anthracis* which is not lethal to the guinea-pig or the mouse, the test may be carried out in guinea-pigs. For a strain which is lethal to the guinea-pig but not to the rabbit, the test may be carried out in rabbits. For a strain which is lethal to some rabbits, carry out the test in sheep.

If the test is carried out in guinea-pigs or in rabbits, use 10 healthy animals (group a). Inject subcutaneously or intradermally into each animal 1/10 of the smallest dose of the vaccine stated on the label for sheep. Observe the animals for 21 days. If more than 2 animals die from non-specific causes, repeat the test. Use as controls 3 animals of the same species and of the same origin.

If the test is carried out in sheep, use 5 healthy animals (group b). Inject subcutaneously or intradermally into each animal 1/10 of the smallest dose of the vaccine stated on the label for sheep. Observe the animals for 21 days. Use as controls 3 sheep of the same origin. Inject subcutaneously into each vaccinated animal of group (a) or group (b) at least 100 MLD and into each control animal 10 MLD of a strain of

B. anthracis pathogenic for the species of animal used in the test. Observe all the animals for 10 days. All the vaccinated animals survive and all the controls die from anthrax during the observation period. If a vaccinated animal dies after the challenge, repeat the test. If in the second test a vaccinated animal dies, the vaccine fails the test.

LABELLING

The label states:

- the strain used for preparation of the vaccine,
- the number of viable spores per millilitre.

01/2005:0744

AUJESZKY'S DISEASE VACCINE (INACTIVATED) FOR PIGS

Vaccinum morbi Aujeszkyi ad suem
inactivatum

DEFINITION

Aujeszky's disease vaccine (inactivated) for pigs consists of a suspension of an appropriate strain of Aujeszky's disease virus inactivated without affecting its immunogenic properties or a suspension of an inactivated fraction of the virus having adequate immunogenic properties.

PRODUCTION

The virus strain is grown in suitable cell cultures (5.2.4). The viral suspension is harvested and inactivated; it may be treated to fragment the virus and the viral fragments may be purified and concentrated.

The test for inactivation is carried out using two passages in the same type of cell culture as that used in the production of the vaccine or cells shown to be at least as sensitive. The quantity of inactivated virus used in the test is equivalent to not less than twenty-five doses of the vaccine. No live virus is detected.

Suitable adjuvants and antimicrobial preservatives may be added. The vaccine may be freeze-dried.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety and immunogenicity. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Safety

- A test is carried out in each category of animals for which the vaccine is intended (sows, fattening pigs). The animals used do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Two doses of vaccine are injected by a recommended route into each of not fewer than ten animals. After 14 days, one dose of vaccine is injected into each of the animals. The animals are observed for a further 14 days. No abnormal local or systemic reaction is produced during the 28 days of the test. If the vaccine is intended for use in pregnant sows, for the test in this category of animal the observation period is prolonged up to farrowing and any effects on gestation or the offspring are noted.
- The animals used in the test for immunogenicity are also used to evaluate safety. The rectal temperature of each vaccinated animal is measured at the time of vaccination and 6 h, 24 h and 48 h later. No animal shows a temperature rise greater than 1.5 °C and the number of animals showing a temperature greater than 41 °C does not exceed 10 per cent of the group. No other systemic reactions (for example, anorexia) are noted. At slaughter,

the injection site is examined for local reactions. No abnormal local reactions attributable to the vaccine are produced.

- C. The animals used for field trials are also used to evaluate safety. A test is carried out in each category of animals for which the vaccine is intended (sows, fattening pigs). Not fewer than three groups each of not fewer than twenty animals are used with corresponding groups of not fewer than ten controls. The rectal temperature of each vaccinated animal is measured at the time of vaccination and 6 h, 24 h and 48 h later. No animal shows a temperature rise greater than 1.5 °C and the number of animals showing a temperature greater than 41 °C does not exceed 25 per cent of the group. At slaughter, the injection site is examined for local reactions. No abnormal local reactions attributable to the vaccine are produced.

Immunogenicity. Not fewer than ten fattening pigs of the age recommended for vaccination and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus are used. The body mass of none of the pigs differs from the average body mass of the group by more than 20 per cent. Each pig is vaccinated according to the recommended schedule and by a recommended route. Five similar pigs are used as controls. At the end of the fattening period (80 kg to 90 kg), each pig is weighed and then challenged by the intranasal route with a suitable quantity of a virulent strain of Aujeszky's disease virus (challenge with at least 10^6 CCID₅₀ of a virulent strain having undergone not more than three passages and administered in not less than 4 ml of diluent has been found to be satisfactory). The titre of challenge virus is determined in swabs taken from the nasal cavity of each animal daily from the day before challenge until virus is no longer detected. Each animal is weighed 7 days after challenge or at the time of death if this occurs earlier and the average daily gain is calculated as a percentage. For each group (vaccinated and controls), the average of the average daily gains is calculated. The vaccine complies with the test if:

- all the vaccinated pigs survive and the difference between the averages of the daily gains for the two groups is not less than 1.5,
- the geometrical mean titres and the duration of excretion of the challenge virus are significantly lower in vaccinates than in controls.

The test is not valid unless all the control pigs display signs of Aujeszky's disease and the average of their daily gains is less than –0.5.

If the vaccine is intended for use in sows for the passive protection of piglets, the suitability of the strain for this purpose may be demonstrated by the following method. Eight sows which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus are vaccinated according to the recommended schedule and by a recommended route; four sows are kept as controls. The piglets from the sows are challenged with a suitable quantity of a virulent strain of Aujeszky's disease virus at 6 to 10 days of age. The piglets are observed for 21 days. The vaccine is satisfactory if not less than 80 per cent protection against mortality is found in the piglets from the vaccinated sows compared to those from the control sows. The test is not valid if the average number of piglets per litter for each group is less than six.

BATCH TESTING

The test described under Potency is not necessarily carried out for routine testing of batches of vaccine. It is carried out for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where

the test is not carried out a suitable, validated, alternative test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

IDENTIFICATION

In animals having no antibodies against Aujeszky's disease virus or against a fraction of the virus, the vaccine stimulates the production of specific antibodies against Aujeszky's disease virus or the fraction of the virus used in the production of the vaccine.

TESTS

Safety. Inject two doses of the vaccine by a recommended route into each of not fewer than two pigs of the minimum age recommended for vaccination and having no antibodies against Aujeszky's disease virus or against a fraction of the virus. Observe the animals for 14 days and then inject one dose of the vaccine into each piglet. Observe the animals for a further 14 days. No abnormal local or systemic reaction occurs during the 28 days of the test.

Inactivation. Wherever possible, carry out a suitable test for residual infectious Aujeszky's disease virus using two passages in the same type of cell culture as used in the production of the vaccine or cells shown to be at least as sensitive. Otherwise, inject one dose of the vaccine subcutaneously into each of five healthy non-immunised rabbits. Observe the animals for 14 days after the injection. No abnormal reaction (in particular a local rash) occurs. If the vaccine strain is not pathogenic for the rabbit, carry out the test in two sheep.

Extraneous viruses. On the pigs used for the safety test carry out tests for antibodies. The vaccine does not stimulate the formation of antibodies, other than those against Aujeszky's disease virus, against viruses pathogenic for pigs or against viruses that could interfere with the diagnosis of infectious diseases of pigs (including the viruses of the pestivirus group).

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Use not fewer than five pigs each weighing 15 kg to 35 kg and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. The body mass of none of the pigs differs from the average body mass of the group by more than 25 per cent. Administer to each pig by a recommended route one dose of the vaccine. Use five similar pigs as controls. Three weeks later weigh each pig and then challenge by the intranasal route with a suitable quantity of a virulent strain of Aujeszky's disease virus. Weigh each animal 7 days after challenge or at the time of death if this occurs earlier and calculate the average daily gain as a percentage. For each group (vaccinated and controls), calculate the average of the average daily gains. The vaccine passes the test if the vaccinated pigs survive and the difference between the averages of the daily gains for the two groups is not less than 1.1. The test is not valid unless all the control pigs display signs of Aujeszky's disease and the average of their daily gains is less than –0.5.

LABELLING

The label states:

- whether the vaccine strain is pathogenic for the rabbit,
- whether the vaccine is a whole-virus vaccine or a subunit vaccine.

01/2005:0745

AUJESZKY'S DISEASE VACCINE (LIVE) FOR PIGS FOR PARENTERAL ADMINISTRATION, FREEZE-DRIED

Vaccinum morbi Aujeszkyi ad suem vivum cryodesiccatum ad usum parenterale

DEFINITION

Freeze-dried Aujeszky's disease vaccine (live) for pigs for parenteral administration is a preparation of an attenuated strain of Aujeszky's disease virus. It may be administered after mixing with an adjuvant.

PRODUCTION

The virus strain is grown in suitable cell cultures (5.2.4) or in fertilised hen eggs from flocks free from specified pathogens (5.2.2). The viral suspension is harvested, mixed with a suitable stabilising liquid and freeze-dried.

CHOICE OF VACCINE STRAIN

Only a virus strain shown to be satisfactory with respect to the following characteristics may be used in the preparation of the vaccine: safety; transmissibility, including transmission across the placenta and by semen; irreversibility of attenuation; immunogenicity. The strain may have a genetic marker. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Safety.

- A. 10 piglets, 3 to 4 weeks old and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus, each receive by a recommended route a quantity of virus corresponding to 10 doses of vaccine. 10 piglets of the same origin and age and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus are kept as controls. The animals are observed for 21 days. The piglets remain in good health. The weight curve of the vaccinated piglets does not differ significantly from that of the controls.
- B. The animals used in the test for immunogenicity are also used to evaluate safety. The rectal temperature of each vaccinated animal is measured at the time of vaccination and 6 h, 24 h and 48 h later. No animal shows a temperature rise greater than 1.5 °C and the number of animals showing a temperature greater than 41 °C does not exceed 10 per cent of the group. No other systemic reactions (for example, anorexia) are noted. At slaughter, the injection site is examined for local reactions. No abnormal local reactions attributable to the vaccine are produced.
- C. The animals used for field trials are also used to evaluate safety. A test is carried out in each category of animals for which the vaccine is intended (sows, fattening pigs). Not fewer than 3 groups each of not fewer than 20 animals are used with corresponding groups of not fewer than 10 controls. The rectal temperature of each animal is measured at the time of vaccination and 6 h, 24 h and 48 h later. No animal shows a temperature rise greater than 1.5 °C and the number of animals showing a temperature greater than 41 °C does not exceed 25 per cent of the group. At slaughter, the injection site is examined for local reactions. No abnormal local reactions attributable to the vaccine are produced.
- D. 10 piglets, 3 to 5 days old and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus, each receive by the intranasal route

a quantity of virus corresponding to 10 doses of vaccine. The animals are observed for 21 days. None of the piglets dies or shows signs of neurological disorder attributable to the vaccine virus.

- E. This test is not necessary for gE-negative strains. 5 piglets, 3 to 5 days old, each receive $10^{4.5}$ CCID₅₀ of vaccine virus intracerebrally. None of the piglets dies or shows signs of neurological disorder.
- F. 10 piglets, 3 to 4 weeks old and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus, each receive a daily injection of 2 mg of prednisolone per kilogram of body mass for 5 consecutive days. On the third day each piglet receives a quantity of virus corresponding to 1 dose of vaccine by a recommended route. Antimicrobial agents may be administered to prevent aspecific signs. Observe the animals for 21 days following administration of the virus. The piglets remain in good health.
- G. 15 pregnant sows which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus are used. Each of 5 sows receive by a recommended route a quantity of virus corresponding to 10 doses of vaccine during the fourth or fifth week of gestation. 5 other sows each receive the same dose of virus by the same route during the tenth or eleventh week of gestation. The other 5 pregnant sows are kept as controls. The number of piglets born to the vaccinated sows, any abnormalities in the piglets and the duration of gestation do not differ significantly from those of the controls. For the piglets from vaccinated sows: carry out tests for serum antibodies against Aujeszky's disease virus; carry out tests for Aujeszky's disease virus antigen in the liver and lungs of those piglets showing abnormalities and in a quarter of the remaining healthy piglets. No Aujeszky's disease virus antigen is found in piglets born to the vaccinated sows and no antibodies against Aujeszky's disease virus are found in the serum taken before ingestion of colostrum.

Virus excretion. 18 pigs, 3 to 4 weeks old and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus are used. 14 of the pigs each receive 1 dose of vaccine by the recommended route and at the recommended site and the remaining 4 pigs are kept as contact controls. Suitably sensitive tests for the virus are carried out individually on the nasal and oral secretions as follows: nasal and oral swabs are collected daily from the day before vaccination until 10 days after vaccination. The vaccine is acceptable if the virus is not isolated from the secretions collected.

Transmissibility. The test is carried out on 4 separate occasions. Each time 4 piglets, 3 to 4 weeks old and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus, each receive by a recommended route a quantity of virus corresponding to 1 dose of vaccine. 1 day after the administration, 2 other piglets of the same age which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus are kept close together with them. After 5 weeks all the animals are tested for the presence of antibodies against Aujeszky's disease virus. Antibodies against Aujeszky's disease virus are not detected in any group of contact controls. All the treated piglets show an antibody response.

Reversion to virulence. 2 piglets, 3 to 5 days old and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus, each receive by the intranasal route a quantity of virus corresponding to 1 dose of vaccine. 3 to 5 days later brain, lung, tonsils and local lymph glands are taken from each piglet and the samples are pooled. 1 ml of the pooled organ suspension is administered

intranasally into each of 2 other piglets of the same age and susceptibility. This operation is then repeated not fewer than 4 times, the last time in not fewer than 5 piglets. The presence of the virus is verified at each passage by direct or indirect means. If the virus has disappeared, a second series of passages is carried out. The piglets do not die or show neurological disorders from causes attributable to the vaccine virus. There is no indication of an increase of virulence as compared with the non-passaged virus.

Immunogenicity. Not fewer than 10 fattening pigs of the age recommended for vaccination and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus are used. The body mass of none of the pigs differs from the average body mass of the group by more than 20 per cent. Each pig is vaccinated according to the recommended schedule and by a recommended route. 5 similar pigs are used as controls. At the end of the fattening period (80 kg to 90 kg), each pig is weighed and then challenged by the intranasal route with a suitable quantity of a virulent strain of Aujeszky's disease virus (challenge with at least 10^6 CCID₅₀ of a virulent strain having undergone not more than 3 passages and administered in not less than 4 ml of diluent has been found to be satisfactory). The titre of virus is determined in swabs taken from the nasal cavity of each pig daily from the day before challenge until virus is no longer detected. Each pig is weighed 7 days after challenge or at the time of death if this occurs earlier and the average daily gain is calculated as a percentage. For each group (vaccinated and controls), the average of the average daily gains is calculated. The vaccine complies with the test if:

- all the vaccinated pigs survive and the difference between the averages of the average daily gains for the 2 groups is not less than 1.5,
- the geometrical mean titres and the duration of excretion of the challenge virus are significantly lower in vaccinates than in controls.

The test is not valid unless all the control pigs display signs of Aujeszky's disease and the average of their average daily gains is less than –0.5.

If the vaccine is intended for use in sows for the passive protection of piglets, the suitability of the strain for this purpose may be demonstrated by the following method. 8 sows which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus are vaccinated according to the recommended schedule and by the recommended route; 4 sows are kept as controls. The piglets from the sows are challenged with a suitable quantity of a virulent strain of Aujeszky's disease virus at 6 to 10 days of age. The piglets are observed for 21 days. The vaccine is satisfactory if not less than 80 per cent protection against mortality is found in the piglets from the vaccinated sows compared to those from the control sows. The test is not valid if the average number of piglets per litter for each group is less than 6.

BATCH TESTING

The test described under Potency is not necessarily carried out for routine testing of batches of vaccine. It is carried out for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out a suitable, validated alternative test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

IDENTIFICATION

In animals having no antibodies against Aujeszky's disease virus or against a fraction of the virus, the vaccine stimulates the production of specific neutralising antibodies.

TESTS

Safety. Administer 10 doses of the vaccine in a suitable volume by a recommended route to each of not fewer than 2 pigs of the minimum age recommended for vaccination and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Observe the animals for 14 days. No abnormal local or systemic reaction occurs.

Extraneous viruses. Neutralise the vaccine using a monospecific antiserum or monoclonal antibodies and inoculate into cell cultures known to be sensitive to viruses pathogenic for pigs and to pestiviruses. Maintain these cultures for 14 days and make at least 1 passage during this period. No cytopathic effect develops; the cells show no evidence of the presence of haemadsorbing agents. Carry out a specific test for pestiviruses.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

Mycoplasmas (2.6.7). The vaccine complies with the test for mycoplasmas.

Virus titre. Titrate the reconstituted vaccine on the same substrate as used for production (cell cultures or inoculation into the allantoic cavity of fertilised hen eggs). 1 dose of the vaccine contains not less than the quantity of virus equivalent to the minimum virus titre stated on the label.

POTENCY

Use not fewer than 5 pigs weighing 15 kg to 35 kg and which do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. The body mass of none of the pigs differs from the average body mass of the group by more than 25 per cent. Administer to each pig by a recommended route 1 dose of the vaccine. Use 5 similar pigs as controls. 3 weeks later weigh each pig and then challenge by the intranasal route with a suitable quantity of a virulent strain of Aujeszky's disease virus. Weigh each animal 7 days after challenge or at the time of death if this occurs earlier and calculate the average daily gain as a percentage. For each group (vaccinated and controls), calculate the average of the average daily gains. The vaccine complies with the test if all the vaccinated pigs survive and the difference between the averages of the average daily gains for the 2 groups is not less than 1.6. The test is not valid unless all the control pigs display signs of Aujeszky's disease and the average of their average daily gains is less than –0.5.

LABELLING

The label states:

- the substrate used for production of the vaccine (cell cultures or eggs),
- the minimum virus titre.

01/2005:0959

AVIAN INFECTIOUS BRONCHITIS VACCINE (INACTIVATED)

Vaccinum bronchitidis infectivae aviariae inactivatum

DEFINITION

Avian infectious bronchitis vaccine (inactivated) consists of an emulsion or a suspension of one or more serotypes of avian infectious bronchitis virus which have been inactivated in such a manner that the immunogenic activity is retained. This monograph describes vaccines intended to protect

against drop of egg production or quality; for vaccines also intended to protect against respiratory symptoms, a demonstration of efficacy additional to that described under Potency is required.

PRODUCTION

The virus is propagated in fertilised hen eggs from healthy flocks (5.2.2) or in suitable cell cultures (5.2.4).

An amplification test for residual live avian infectious bronchitis virus is carried out on each batch of antigen immediately after inactivation and on the final bulk vaccine or, if the vaccine contains an adjuvant, on the bulk antigen or the mixture of bulk antigens immediately before the addition of adjuvant; the test is carried out in fertilised hen eggs from flocks free from specified pathogens (5.2.2) or in suitable cell cultures (5.2.4) and the quantity of inactivated virus used is equivalent to not less than 10 doses of vaccine. No live virus is detected.

The vaccine may contain one or more suitable adjuvants.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety and immunogenicity for each category of chickens for which it is intended. The following test may be used during demonstration of efficacy (5.2.7).

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity.

BATCH POTENCY TEST

The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established by a statistical evaluation.

Administer 1 dose of vaccine intramuscularly to each of ten chickens, between 2 weeks of age and the minimum age stated for vaccination and from a flock free from specified pathogens and keep five hatch mates as unvaccinated controls. Collect serum samples from each chicken just before administration of the vaccine and after the period defined when testing the reference vaccine; determine the antibody titre of each serum, for each serotype in the vaccine, by a suitable serological method, for example, serum neutralisation. The antibody levels are not significantly less than those obtained with a batch that has given satisfactory results in the test described under Potency (reference vaccine). The test is not valid unless the sera collected from the unvaccinated controls and from the chickens just before the administration of the vaccine are free from detectable specific antibody.

IDENTIFICATION

In susceptible animals, the vaccine stimulates the production of specific antibodies against each of the virus serotypes in the vaccine, detectable by virus neutralisation.

TESTS

Safety. Inject a double dose of vaccine by a recommended route into each of ten 14- to 28-day-old chickens from a flock free from specified pathogens (5.2.2). Observe the chickens for 21 days. No abnormal local or systemic reaction occurs.

Inactivation.

A. For vaccine prepared with embryo-adapted strains of virus, inject two-fifths of a dose into the allantoic cavity of ten 9- to 11-day-old fertilised hen eggs from a flock free from specified pathogens (SPF hen eggs) (5.2.2) and incubate. Observe for 5 to 6 days and pool separately the allantoic liquid from eggs containing live embryos and that from eggs containing dead embryos, excluding those that die within the first 24 h after injection. Examine for abnormalities all embryos which die after 24 h of injection or which survive 5 to 6 days. No death or abnormality attributable to the vaccine virus occurs.

Inject into the allantoic cavity of each of ten 9- to 11-day-old fertilised SPF hen eggs 0.2 ml of the pooled allantoic liquid from the live embryos and into each of ten similar eggs 0.2 ml of the pooled liquid from the dead embryos and incubate for 5 to 6 days. Examine for abnormalities all embryos which die after 24 h of injection or which survive 5 to 6 days. No death or abnormality attributable to the vaccine virus occurs.

If more than 20 per cent of the embryos die at either stage repeat the test from that stage. The vaccine complies with the test if there is no death or abnormality attributable to the vaccine virus.

B. For vaccine prepared with cell-culture-adapted strains of virus, inoculate ten doses of the vaccine into suitable cell cultures. If the vaccine contains an oil adjuvant, eliminate it by suitable means. Incubate at 38 ± 1 °C for 7 days. Make a passage on another set of cell cultures and incubate at 38 ± 1 °C for 7 days. None of the cultures shows signs of infection.

Extraneous agents. Use the chickens from the test for safety. 21 days after injection of the double dose of vaccine, inject one dose by the same route into each chicken. Collect serum samples from each chicken 2 weeks later and carry out tests for antibodies to the following agents by the methods prescribed for *chicken flocks free from specified pathogens for the production and quality control of vaccines* (5.2.2): avian encephalomyelitis virus, avian leucosis viruses, haemagglutinating avian adenovirus, infectious bursal disease virus, infectious laryngotracheitis virus, influenza A virus, Marek's disease virus, Newcastle disease virus. The vaccine does not stimulate the formation of antibodies against these agents.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Carry out a potency test for each serotype in the vaccine. Use four groups of not fewer than thirty chickens from a flock free from specified pathogens (5.2.2.), treated as follows:

Group A: unvaccinated controls.

Group B: vaccinated with inactivated avian infectious bronchitis vaccine.

Group C: vaccinated with live avian infectious bronchitis vaccine and inactivated avian infectious bronchitis vaccine according to the recommended schedule.

Group D: vaccinated with live avian infectious bronchitis vaccine.

Monitor egg production and quality in all birds from point of lay until at least 4 weeks after challenge. At the peak of lay, challenge all groups with a quantity of virulent avian infectious bronchitis virus sufficient to cause a drop in egg production or quality over three consecutive weeks during the 4 weeks following challenge. The vaccine complies with the test if egg production or quality is significantly

better in group C than in group D and significantly better in group B than in group A. The test is not valid unless there is a drop in egg production in group A compared to the normal level noted before challenge of at least 35 per cent where challenge has been made with a Massachusetts-type strain; where it is necessary to carry out a challenge with a strain of another serotype for which there is documented evidence that the strain will not cause a 35 per cent drop in egg production, the challenge must produce a drop in egg production commensurate with the documented evidence and in any case not less than 15 per cent.

LABELLING

The label states:

- the category and age of the chickens for which the vaccine is intended,
- the strains and serotypes of virus used in the production of the vaccine and the serotypes against which the vaccine is intended to protect,
- whether the strain in the vaccine is embryo-adapted or cell-culture-adapted.

01/2005:0442

AVIAN INFECTIOUS BRONCHITIS VACCINE (LIVE)

Vaccinum bronchitidis infectivae aviariae vivum

1. DEFINITION

Avian infectious bronchitis vaccine (live) is a preparation of one or more suitable strains of different types of avian infectious bronchitis virus. This monograph applies to vaccines intended for administration to chickens for active immunisation against respiratory disease caused by avian infectious bronchitis virus.

2. PRODUCTION

2-1. PREPARATION OF THE VACCINE

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. SUBSTRATE FOR VIRUS PROPAGATION

2-2-1. Embryonated hens' eggs. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (5.2.2).

2-2-2. Cell cultures. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (5.2.4).

2-3. SEED LOTS

2-3-1. Extraneous agents. The master seed lot complies with the tests for extraneous agents in seed lots (2.6.24). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the test.

2-4. CHOICE OF VACCINE VIRUS

The vaccine virus shall be shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during the demonstration of safety and immunogenicity.

2-4-1. Safety

2-4-1-1. Safety for the respiratory tract and kidneys. Carry out the test in chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. Use not fewer than 15 chickens from an SPF flock (5.2.2) and from the same origin. Administer to each chicken by the oculonasal route a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. On each of days 5, 7 and 10 after administration of the virus, kill not fewer than 5 of the chickens, take samples of trachea and kidney. Fix kidney samples for histological examination. Remove the tracheas and cut 10 rings from each trachea (3 from the top, 4 from the mid-part and 3 from the bottom); examine each ring under low magnification and score for ciliostasis on a scale from 0 (100 per cent ciliary activity) to 4 (no activity, complete ciliostasis); calculate the mean ciliostasis score (the maximum for each trachea being 40) for the 5 chickens killed on each of days 5, 7 and 10. The test is not valid if more than 10 per cent of the chickens die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if:

- no chicken shows notable clinical signs of avian infectious bronchitis or dies from causes attributable to the vaccine virus,
- the average ciliostasis score is not more than 25,
- at most moderate inflammatory lesions are seen during kidney histological examination.

2-4-1-2. Safety for the reproductive tract. If the recommendations for use state or imply that the vaccine may be used in females of less than 3 weeks old that are subsequently kept to sexual maturity, it shall be demonstrated that there is no damage to development of the reproductive tract when the vaccine is given to chickens of the minimum age to be recommended for vaccination. The following test may be carried out: use not fewer than 40 female chickens not older than the minimum age recommended for vaccination and from an SPF flock (5.2.2); use the vaccine virus at the least attenuated passage level that will be present in a batch of vaccine; administer to each chicken by a recommended route a quantity of virus equivalent to not less than the maximum titre likely to be present in 1 dose of vaccine; at least 10 weeks after administration of the vaccine virus, kill the chickens and carry out macroscopic examination of the oviducts. The vaccine virus complies with the test if abnormalities are present in not more than 5 per cent of the oviducts.

2-4-2. Increase in virulence. The test for increase in virulence consists of the administration of the vaccine virus, at the least attenuated virus passage level that will be present between the master seed lot and a batch of the vaccine, to a group of five 2-week-old chickens from an SPF flock (5.2.2), sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by eye-drop a quantity of the vaccine virus that will allow recovery of virus for the passages described below. 2 to 4 days after administration of the vaccine virus, prepare a suspension from the mucosa of the trachea of each chicken and pool these samples. Administer 0.05 ml of the pooled samples by eye-drop to each of 5

other 2-week-old chickens from an SPF flock (5.2.2). Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for safety for the respiratory tract and kidney (section 2-4-1-1) and, where applicable, the test for safety for the reproductive tract (section 2-4-1-2) using the unpassaged vaccine virus and the maximally passaged virus that has been recovered. Administer the virus by the route to be recommended for vaccination likely to be the least safe. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. Immunogenicity. Immunogenicity is demonstrated for each strain of virus to be included in the vaccine. A test is carried out for each route and method of administration to be recommended using in each case chickens from an SPF flock (5.2.2) not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each chicken is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. 1 or both of the tests below may be used during the demonstration of immunogenicity.

2-4-3-1. Ciliary activity of tracheal explants. Use not fewer than 25 chickens of the same origin and from an SPF flock (5.2.2). Vaccinate by a recommended route not fewer than 20 chickens. Maintain not fewer than 5 chickens as controls. Challenge each chicken after 21 days by eye-drop with a sufficient quantity of virulent avian infectious bronchitis virus of the same type as the vaccine virus to be tested. Kill the chickens 4 to 7 days after challenge and prepare transverse sections from the upper part (3), the middle part (4) and the lower part (3) of the trachea of each chicken. Examine all explants as soon as possible and at the latest 2 h after sampling by low-magnification microscopy for ciliary activity. For a given tracheal section, ciliary activity is considered as normal when at least 50 per cent of the internal ring shows vigorous ciliary movement. A chicken is considered not affected if not fewer than 9 out of 10 rings show normal ciliary activity.

The test is not valid if:

- fewer than 80 per cent of the control chickens show cessation or extreme loss of vigour of ciliary activity,
- and/or during the period between the vaccination and challenge more than 10 per cent of vaccinated or control chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if not fewer than 80 per cent of the vaccinated chickens show normal ciliary activity.

2-4-3-2. Virus recovery from tracheal swabs. Use not fewer than 30 chickens of the same origin and from an SPF flock (5.2.2). Vaccinate by a recommended route not fewer than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 21 days by eye-drop with a sufficient quantity of virulent avian infectious bronchitis virus of the same type as the vaccine virus to be tested. Kill the chickens 4 to 7 days after challenge and prepare a suspension from swabs of the tracheal mucosa of each chicken. Inoculate 0.2 ml of the suspension into the allantoic cavity of each of 5 embryonated hens' eggs, 9 to 11 days old, from an SPF flock (5.2.2). Incubate the eggs for 6-8 days after inoculation. Eggs that after 1 day of incubation do not contain a live embryo are eliminated and considered as

non-specific deaths. Record the other eggs containing a dead embryo and after 6-8 days' incubation examine each egg containing a live embryo for lesions characteristic of avian infectious bronchitis. Make successively 3 such passages. If 1 embryo of a series of eggs dies or shows characteristic lesions, the inoculum is considered to be a carrier of avian infectious bronchitis virus. The examination of a series of eggs is considered to be definitely negative if no inoculum concerned is a carrier. The test is not valid if:

- the challenge virus is re-isolated from fewer than 80 per cent of the control chickens,
- and/or during the period between vaccination and challenge more than 10 per cent of the vaccinated or control chickens show abnormal clinical signs or die from causes not attributable to the vaccine,
- and/or more than 1 egg in any group is eliminated because of non-specific embryo death.

The vaccine virus complies with the test if the challenge virus is re-isolated from not more than 20 per cent of the vaccinated chickens.

3. BATCH TESTS

3-1. Identification

3-1-1. Vaccines containing one type of virus. The vaccine, diluted if necessary and mixed with avian infectious bronchitis virus antiserum specific for the virus type, no longer infects embryonated hens' eggs from an SPF flock (5.2.2) or susceptible cell cultures (5.2.4) into which it is inoculated.

3-1-2. Vaccines containing more than one type of virus. The vaccine, diluted if necessary and mixed with type-specific antisera against each strain present in the vaccine except that to be identified, infects embryonated hens' eggs from an SPF flock (5.2.2) or susceptible cell cultures (5.2.4) into which it is inoculated whereas after further admixture with type-specific antiserum against the strain to be identified it no longer produces such infection.

3-2. Bacteria and fungi

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. Mycoplasmas. The vaccine complies with the test for mycoplasmas (2.6.7).

3-4. Extraneous agents. The vaccine complies with the tests for extraneous agents in batches of finished product (2.6.25).

3-5. Safety. Use not fewer than 10 chickens from an SPF flock (5.2.2) and of the youngest age recommended for vaccination. Administer by a recommended route to each chicken, 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre.** Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (5.2.2) or into suitable cell cultures (5.2.4). If the vaccine contains more than 1 strain of virus, titrate each strain after having neutralised the others with type-specific avian infectious bronchitis antisera. The vaccine complies with the test if 1 dose contains for each vaccine virus not less than the minimum titre stated on the label.

3-7. **Potency.** The vaccine complies with the requirements of 1 of the tests prescribed under Immunogenicity (section 2-4-3) when administered according to the recommended schedule by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2005:0960

AVIAN INFECTIOUS BURSAL DISEASE VACCINE (INACTIVATED)

Vaccinum bursitidis infectivae aviariae inactivatum

DEFINITION

Inactivated infectious avian bursal disease vaccine consists of an emulsion or a suspension of a suitable strain of infectious avian bursal disease virus type 1 which has been inactivated in such a manner that immunogenic activity is retained. The vaccine is for use in breeding domestic fowl to protect their progeny from infectious avian bursal disease.

PRODUCTION

The virus is propagated in fertilised eggs from healthy flocks, in suitable cell cultures (5.2.4) or in chickens from a flock free from specified pathogens (5.2.2).

An amplification test for residual live infectious avian bursal disease virus is carried out on each batch of antigen immediately after inactivation and on the final bulk vaccine or, if the vaccine contains an adjuvant, on the bulk antigen or the mixture of bulk antigens immediately before the addition of any adjuvant, to confirm inactivation; the test is carried out in fertilised hen eggs or in suitable cell cultures or, where chickens have been used for production of the vaccine, in chickens from a flock free from specified pathogens (5.2.2); the quantity of inactivated virus used in the test is equivalent to not less than ten doses of the vaccine. No live virus is detected.

The vaccine may contain one or more suitable adjuvants.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and immunogenicity (5.2.7). The following test may be used during demonstration of efficacy.

Immunogenicity. Each of at least twenty chickens from a flock free from specified pathogens (5.2.2), and of the recommended age for vaccination (close to the point of lay), is injected with the minimum recommended dose of vaccine by one of the recommended routes. 4 to 6 weeks later serum samples are collected from each bird and the antibody response is measured in a serum-neutralisation (SN) test. A suitable standard, calibrated in Ph. Eur. Units against *infectious avian bursal disease serum BRP*, is included in the test. The vaccine complies with the test if the mean antibody level in the sera from the vaccinated birds is at least 10 000 Ph. Eur. Units per millilitre.

Eggs are collected for hatching 5 to 7 weeks after vaccination and the test described below is carried out with 3-week-old chickens from that egg collection. Eggs are collected again towards the end of the period of lay and the test is repeated with chickens from that egg collection which are at least 15 days old.

Twenty-five chickens from vaccinated hens and ten control chickens of the same breed and age from unvaccinated hens are challenged with an eye-drop application of a quantity of a virulent strain of infectious avian bursal disease virus sufficient to produce severe signs of disease, including lesions of the bursa of Fabricius, in all unvaccinated chickens. 3 to 4 days after challenge, the bursa of Fabricius is removed from each chicken. The bursae are examined for evidence of infection by histological examination or by testing for the presence of infectious avian bursal disease antigen in an agar-gel precipitation test. The vaccine complies with the test if three or fewer of the chickens from vaccinated hens show evidence of infectious avian bursal disease infection. The test is not valid unless all the chickens from unvaccinated hens are affected.

Where there is more than one recommended route of administration, the test described under Potency is carried out in parallel with the above immunogenicity test, using different groups of birds for each recommended route. The serological response of the birds inoculated by routes other than that used in the immunogenicity test is not significantly less than that of the group vaccinated by that route.

IDENTIFICATION

In chickens with no antibodies to infectious avian bursal disease virus type 1, the vaccine stimulates the production of specific antibodies.

TESTS

Safety. Inject twice the vaccinating dose by one of the recommended routes into each of ten chickens, 14 to 28 days old, from flocks free from specified pathogens (5.2.2). Observe the birds for 21 days. No abnormal local or systemic reaction occurs. *Note: this test may be omitted if inactivation test C is carried out.*

Inactivation

A. For vaccine prepared with embryo-adapted strains of virus, inject two-fifths of a dose into the allantoic cavity or onto the chorio-allantoic membrane of ten 9- to 11-day-old fertilised hen eggs from a flock free from specified pathogens (SPF eggs) (5.2.2). Incubate the eggs and observe for 6 days. Pool separately the allantoic liquid or membranes from eggs containing live embryos, and that from eggs containing dead embryos, excluding those that die from non-specific causes within 24 h of the injection.

Inject into the allantoic cavity or onto the chorio-allantoic membrane of each of ten 9- to 11-day-old SPF eggs 0.2 ml of the pooled allantoic liquid or crushed chorio-allantoic membranes from the live embryos and, into each of ten similar eggs, 0.2 ml of the pooled liquid or membranes from the dead embryos and incubate for 6 days. Examine each embryo for lesions of infectious avian bursal disease.

If more than 20 per cent of the embryos die at either stage repeat that stage. The vaccine complies with the test if there is no evidence of lesions of infectious avian bursal disease and if, in any repeat test, not more than 20 per cent of the embryos die from non-specific causes.

Antibiotics may be used in the test to control extraneous bacterial infection.

01/2005:0587

- B. For vaccine prepared with cell-culture-adapted strains of virus, inoculate ten doses of the vaccine into suitable cell cultures. If the vaccine contains an oil adjuvant, eliminate it by suitable means. Incubate at 38 ± 1 °C for 7 days. Make a passage on another set of cell cultures and incubate at 38 ± 1 °C for 7 days. The cultures show no signs of infection.
- C. For vaccine prepared with strains of virus not adapted to embryos or cell cultures, inject two doses intramuscularly into each of twenty 14- to 28-day-old chickens from flocks free from specified pathogens (5.2.2). 4 days later, kill ten of the chickens and remove the bursa of Fabricius from each chicken. Pool the bursae and homogenise in an equal volume of a suitable liquid. Inject 1 ml of the bursal homogenate into each of a further ten chickens of the same age and from the same source. Examine microscopically the bursa of Fabricius of each remaining chicken from the first group and of each chicken from the second group 21 days after the injection; there is no evidence of infectious avian bursal disease infection. In addition there are no signs of any disease attributable to the vaccine and no abnormal local reaction develops. The chickens of the second group do not have antibodies against infectious avian bursal disease virus when examined 21 days after the injection.

Extraneous agents. Collect serum samples from each of the birds used in the safety test or inactivation test C, three weeks after vaccination. Carry out tests for antibodies to the following agents by the methods prescribed for *chicken flocks free from specified pathogens for the production and quality control of vaccines* (5.2.2): avian encephalomyelitis virus, avian leucosis viruses, haemagglutinating avian adenovirus, infectious bronchitis virus, infectious laryngotracheitis virus, influenza A virus, Marek's disease virus, Newcastle disease virus. The vaccine does not stimulate the formation of antibodies against these agents.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Vaccinate each of not fewer than ten chickens, 4 weeks of age and from a flock free from specified pathogens (5.2.2), with one dose of vaccine by one of the recommended routes. 4 to 6 weeks later, collect serum samples from each bird and ten unvaccinated control birds of the same age and from the same source. Measure the antibody response in a serum-neutralisation test. Include in the test a suitable standard, calibrated in Ph.Eur. Units against *infectious avian bursal disease serum BRP*. The mean antibody level in the sera from the vaccinated birds is not less than 10 000 Ph. Eur. Units per millilitre. There are no antibodies in the sera of the unvaccinated birds.

LABELLING

The label states whether the strain in the vaccine is embryo-adapted or cell-culture-adapted.

AVIAN INFECTIOUS BURSAL DISEASE VACCINE (LIVE)

Vaccinum bursitidis infectivae aviariae vivum

1. DEFINITION

Avian infectious bursal disease vaccine (live) [Gumboro disease vaccine (live)] is a preparation of a suitable strain of infectious bursal disease virus type 1. This monograph applies to vaccines intended for administration to chickens for active immunisation; it applies to vaccines containing strains of low virulence but not to those containing strains of higher virulence that may be needed for disease control in certain epidemiological situations.

2. PRODUCTION

2-1. PREPARATION OF THE VACCINE

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. SUBSTRATE FOR VIRUS PROPAGATION

2-2-1. Embryonated hens' eggs. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (5.2.2).

2-2-2. Cell cultures. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (5.2.4).

2-3. SEED LOTS

2-3-1. Extraneous agents. The master seed lot complies with the tests for extraneous agents in seed lots (2.6.24). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. CHOICE OF VACCINE VIRUS

The vaccine virus shall be shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), damage to the bursa of Fabricius (section 2-4-2), immunosuppression (section 2-4-3), increase in virulence (section 2-4-4) and immunogenicity (section 2-4-5) may be used during the demonstration of safety and immunogenicity.

2-4-1. Safety. Carry out the test for each route and method of administration to be recommended for vaccination using in each case chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test, use not fewer than 20 chickens from an SPF flock (5.2.2). Administer to each chicken a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 10 per cent of the chickens die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no chicken shows notable clinical signs of avian infectious bursal disease or dies from causes attributable to the vaccine virus.

2-4-2. Damage to the bursa of Fabricius. Carry out the test for the route to be recommended for vaccination likely to be the least safe using chickens not older than the youngest age to be recommended for vaccination. Use virus at the least attenuated passage level that will be present between

the master seed lot and a batch of the vaccine. Use not fewer than 20 chickens from an SPF flock (5.2.2). Administer to each chicken a quantity of the vaccine virus equivalent to 10 times the maximum titre likely to be contained in a dose of the vaccine. On each of days 7, 14, 21 and 28 after administration of the vaccine virus, kill not fewer than 5 chickens and prepare a section from the site with the greatest diameters of the bursa of Fabricius of each chicken. Carry out histological examination of the section and score the degree of bursal damage using the following scale.

- | | |
|---|---|
| 0 | No lesion, normal bursa. |
| 1 | 1 per cent to 25 per cent of the follicles show lymphoid depletion (i.e. less than 50 per cent depletion in 1 affected follicle) influx of heterophils in lesions. |
| 2 | 26 per cent to 50 per cent of the follicles show nearly complete lymphoid depletion (i.e. more than 75 per cent depletion in 1 affected follicle), affected follicles show necrosis and severe influx of heterophils may be detected. |
| 3 | 51 per cent to 75 per cent of the follicles show lymphoid depletion; affected follicles show necrosis and severe influx of heterophils is detected. |
| 4 | 76 per cent to 100 per cent of the follicles show nearly complete lymphoid depletion, hyperplasia and cyst structures are detected; affected follicles show necrosis and severe influx of heterophils is detected. |
| 5 | 100 per cent of the follicles show nearly complete lymphoid depletion; complete loss of follicular structure, thickened and folded epithelium, fibrosis of bursal tissue. |

Calculate the average score for each group of chickens. The vaccine virus complies with the test if:

- no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine virus,
- the average score for bursal damage 21 days after administration of the vaccine virus is less than or equal to 2.0 and 28 days after administration is less than or equal to 0.6,
- during the 21 days after administration a notable repopulation of the bursae by lymphocytes has taken place.

2-4-3. Immunosuppression. Carry out the tests for the route recommended for vaccination likely to be the least safe using chickens not older than the youngest age recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. Use not fewer than 30 chickens from an SPF flock (5.2.2). Divide them randomly into 3 groups each of not fewer than 10 and maintain the groups separately. Administer by eye-drop to each chicken of 1 group a quantity of the vaccine virus equivalent to not less than the maximum titre likely to be contained in 1 dose of the vaccine. At the time after administration when maximal bursal damage is likely to be present, as judged from the results obtained in the test for damage to the bursa of Fabricius (section 2-4-2), administer to each vaccinated chicken and to each chicken of another group 1 dose of Hitchner B1 strain Newcastle disease vaccine (live). Determine the seroresponse of each chicken of the 2 groups to the Newcastle disease virus 14 days after administration. Challenge each chicken of the 3 groups by the intramuscular route with not less than 10^5 EID₅₀ of virulent Newcastle disease virus and note the degree of protection in the 2 groups vaccinated with

Hitchner B1 strain Newcastle vaccine compared with the non-vaccinated group. The test is not valid if 1 or more of the non-vaccinated chickens does not die within 7 days of challenge. The degree of immunosuppression is estimated from the comparative seroresponses and protection rates of the 2 Hitchner B1 vaccinated groups. The vaccine complies with the test if there is no significant difference between the 2 groups.

2-4-4. Increase in virulence. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to a group of 5 chickens from an SPF flock (5.2.2) and not older than the youngest age to be recommended for vaccination, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by eye-drop a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Prepare 3 to 4 days after administration a suspension from the bursa of Fabricius of each chicken and pool these samples. Administer 0.05 ml of the pooled samples by eye-drop to each of 5 other chickens of the same age and origin. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for damage to the bursa of Fabricius (section 2-4-2) using the unpassaged vaccine virus and the maximally passaged virus that has been recovered. Administer the virus by the route recommended for vaccination likely to be the least safe. The vaccine virus complies with the test if no indication of increasing virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-5. Immunogenicity. A test is carried out for each route and method of administration to be recommended using in each case chickens not older than the youngest age to be recommended for vaccination. The quantity of vaccine virus administered to each chicken is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. Use not fewer than 30 chickens of the same origin and from an SPF flock (5.2.2). Vaccinate by a recommended route not fewer than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 14 days by eye-drop with a sufficient quantity of virulent avian infectious bursal disease virus. Observe the chickens at least daily for 10 days after challenge. Record the deaths due to infectious bursal disease and the surviving chickens that show clinical signs of disease. At the end of the observation period, kill all the surviving chickens and carry out histological examination for lesions of the bursa of Fabricius. The test is not valid if one or more of the following applies:

- during the observation period following challenge, fewer than 50 per cent of the control chickens show characteristic signs of avian infectious bursal disease,
- 1 or more of the surviving control chickens does not show degree 3 lesions of the bursa of Fabricius,

- during the period between the vaccination and challenge more than 10 per cent of the vaccinated or control chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not fewer than 90 per cent of the vaccinated chickens survive and show no notable clinical signs of disease nor degree 3 lesions of the bursa of Fabricius.

3. BATCH TESTS

3-1. Identification. The vaccine, diluted if necessary and mixed with a monospecific infectious bursal disease virus type 1 antiserum, no longer infects embryonated hens' eggs from an SPF flock (5.2.2) or susceptible cell cultures (5.2.4) into which it is inoculated.

3-2. Bacteria and fungi

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. Mycoplasmas. The vaccine complies with the test for mycoplasmas (2.6.7).

3-4. Extraneous agents. The vaccine complies with the tests for extraneous agents in batches of finished product (2.6.25).

3-5. Safety. Use not fewer than 10 chickens from an SPF flock (5.2.2) and of the youngest age recommended for vaccination. Administer by a recommended route and method to each chicken 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. Virus titre. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (5.2.2) or into suitable cell cultures (5.2.4). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. Potency. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-4-5) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2005:0588

AVIAN INFECTIOUS ENCEPHALOMYELITIS VACCINE (LIVE)

Vaccinum encephalomyelitidis infectivae aviariae vivum

1. DEFINITION

Avian infectious encephalomyelitis vaccine (live) is a preparation of a suitable strain of avian encephalomyelitis virus. This monograph applies to vaccines intended for administration to non-laying breeder chickens to protect passively their future progeny and/or to prevent vertical transmission of virus via the egg.

2. PRODUCTION

2-1. PREPARATION OF THE VACCINE

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. SUBSTRATE FOR VIRUS PROPAGATION

2-2-1. Embryonated hens' eggs. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (5.2.2).

2-2-2. Cell cultures. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (5.2.4).

2-3. SEED LOTS

2-3-1. Extraneous agents. The master seed lot complies with the tests for extraneous agents in seed lots (2.6.24). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. CHOICE OF VACCINE VIRUS

The vaccine virus shall be shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during the demonstration of safety and immunogenicity.

2-4-1. Safety. Carry out the test for each route and method of administration to be recommended for vaccination using in each case non-laying breeder chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test, use not fewer than 20 chickens from an SPF flock (5.2.2). Administer to each chicken a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 10 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no chicken shows notable clinical signs of avian infectious encephalomyelitis or dies from causes attributable to the vaccine virus.

2-4-2. Increase in virulence. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of vaccine to a group of five 1-day-old chickens from an SPF flock (5.2.2), sequential passages, 5 times where possible, to further

similar groups of 1-day-old chickens, and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by a recommended route and method, a quantity of the vaccine virus that will allow recovery of virus for the passages described below. 5 to 7 days later, prepare a suspension from the brain of each chick and pool these samples. Administer a suitable volume of the pooled samples by the oral route to each of 5 other chickens of the same age and origin. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for safety (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged vaccine virus that has been recovered. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. Immunogenicity. If the vaccine is recommended for passive protection of future progeny carry out test 2-4-3-1. If the vaccine is recommended for prevention of vertical transmission of virus via the egg, carry out test 2-4-3-2. A test is carried out for each route and method of administration to be recommended, using in each case chickens from an SPF flock (5.2.2) not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each chicken is not greater than the minimum titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine.

2-4-3-1. Passive immunity in chickens. Vaccinate not fewer than 20 breeder chickens from an SPF flock (5.2.2). Maintain separately not fewer than 10 breeder chickens of the same age and origin as controls. At the peak of lay, hatch not fewer than 25 chickens from eggs from vaccinated breeder chickens and 10 chickens from non-vaccinated breeder chickens. At 2 weeks of age, challenge each chicken by the intracerebral route with a sufficient quantity of virulent avian encephalomyelitis virus. Observe the chickens at least daily for 21 days after challenge. Record the deaths and the number of surviving chickens that show clinical signs of disease. The test is not valid if:

- during the observation period after challenge fewer than 80 per cent of the control chickens die or show severe clinical signs of avian infectious encephalomyelitis,
- and/or during the period between the vaccination and challenge more than 15 per cent of control or vaccinated chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not fewer than 80 per cent of the progeny of vaccinated chickens survive and show no notable clinical signs of disease.

2-4-3-2. Passive immunity in embryos. Vaccinate not fewer than 20 breeder chickens from an SPF flock (5.2.2). Maintain separately not fewer than 10 breeder chickens of the same age and origin as controls. At the peak of lay, incubate

not fewer than 36 eggs from the 2 groups, vaccinated and controls, and carry out an embryo sensitivity test. On the sixth day of incubation inoculate 100 EID₅₀ of the Van Roekel strain of avian encephalomyelitis virus into the yolk sacs of the eggs. 12 days after inoculation examine the embryos for specific lesions of avian encephalomyelitis (muscular atrophy). Deaths during the first 24 h are considered to be non-specific. The test is not valid if fewer than 80 per cent of the control embryos show lesions of avian encephalomyelitis. The test is not valid if fewer than 80 per cent of the embryos can be given an assessment. The vaccine virus complies with the test if not fewer than 80 per cent of the embryos in the vaccinated group show no lesions of avian encephalomyelitis.

3. BATCH TESTS

3-1. Identification. The vaccine, diluted if necessary and mixed with a monospecific avian encephalomyelitis virus antiserum, no longer infects embryonated hens' eggs from an SPF flock (5.2.2) or susceptible cell cultures (5.2.4) into which it is inoculated.

3-2. Bacteria and fungi

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062).

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062) or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062).

3-3. Mycoplasmas. The vaccine complies with the test for mycoplasmas (2.6.7).

3-4. Extraneous agents. The vaccine complies with the tests for extraneous agents in batches of finished product (2.6.25).

3-5. Safety. Use not fewer than 10 chickens not older than the minimum age recommended for vaccination and from an SPF flock (5.2.2). Administer by a recommended route and method to each chicken 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. Virus titre. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (5.2.2) or into suitable cell cultures (5.2.4). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. Potency. Depending on the indications, the vaccine complies with the requirements of 1 or both of the tests prescribed under Immunogenicity (section 2-4-3-1, 2-4-3-2), when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2005:1068

AVIAN INFECTIOUS LARYNGOTRACHEITIS VACCINE (LIVE)

Vaccinum laryngotracheitidis infectivae aviariae vivum

1. DEFINITION

Avian infectious laryngotracheitis vaccine (live) is a preparation of a suitable strain of avian infectious laryngotracheitis virus (gallid herpesvirus 1). This monograph applies to vaccines intended for administration to chickens for active immunisation.

2. PRODUCTION

2-1. PREPARATION OF THE VACCINE

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. SUBSTRATE FOR VIRUS PROPAGATION

2-2-1. Embryonated hens' eggs. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (5.2.2).

2-2-2. Cell cultures. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (5.2.4).

2-3. SEED LOTS

2-3-1. Extraneous agents. The master seed lot complies with the tests for extraneous agents in seed lots (2.6.24). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. CHOICE OF VACCINE VIRUS

The vaccine virus shall be shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) for the chickens for which it is intended.

The following tests for index of respiratory virulence (section 2-4-1), safety (section 2-4-2), increase in virulence (section 2-4-3) and immunogenicity (section 2-4-4) may be used during the demonstration of safety and immunogenicity.

2-4-1. Index of respiratory virulence. Use for the test not fewer than sixty 10-day-old chickens from an SPF flock (5.2.2). Divide them randomly into 3 groups, maintained separately. Prepare 2 tenfold serial dilutions starting from a suspension of the vaccine virus having a titre of 10^5 EID₅₀ or 10^5 CCID₅₀ per 0.2 ml or, if not possible, having the maximum attainable titre. Use vaccine virus at the least attenuated passage level that will be present in a batch of the vaccine. Allocate the undiluted virus suspension and the 2 virus dilutions each to a different group of chickens. Administer by the intratracheal route to each chicken 0.2 ml of the virus suspension attributed to its group. Observe the chickens for 10 days after administration and record the number of deaths. The index of respiratory virulence is the total number of deaths in the 3 groups divided by the total number of chickens. The vaccine virus complies with the test if its index of respiratory virulence is not greater than 0.33.

2-4-2. Safety. Carry out the test for each route and method of administration to be recommended for vaccination, using in each case chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between

the master seed lot and a batch of the vaccine. For each test use not fewer than 20 chickens, from an SPF flock (5.2.2). Administer to each chicken a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 10 per cent of the chickens die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no chicken shows notable clinical signs of avian infectious laryngotracheitis or dies from causes attributable to the vaccine virus.

2-4-3. Increase in virulence. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to a group of 5 chickens not more than 2 weeks old, from an SPF flock (5.2.2), sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by eye-drop a quantity of the vaccine virus that will allow recovery of virus for the passages described below. After the period shown to correspond to maximum replication of the virus, prepare a suspension from the mucosae of suitable parts of the respiratory tract of each chicken and pool these samples. Administer 0.05 ml of the pooled samples by eye-drop to each of 5 other chickens that are 2 weeks old and from an SPF flock (5.2.2). Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Determine the index of respiratory virulence (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged virus that has been recovered; if the titre of the maximally passaged virus is less than 10^5 EID₅₀ or 10^5 CCID₅₀, prepare the tenfold, serial dilutions using the highest titre available. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-4. Immunogenicity. A test is carried out for each route and method of administration to be recommended using in each case chickens not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each chicken is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. Use for the test not fewer than 30 chickens of the same origin and from an SPF flock (5.2.2). Vaccinate by a recommended route not fewer than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 21 days by the intratracheal route with a sufficient quantity of virulent infectious laryngotracheitis virus. Observe the chickens at least daily for 7 days after challenge. Record the deaths and the number of surviving chickens that show clinical signs of disease. At the end of the observation period kill all the surviving chickens and carry out examination for macroscopic lesions: mucoid, haemorrhagic and pseudomembranous inflammation of the trachea and orbital sinuses. The test is not valid if:

01/2005:1392

- during the observation period after challenge fewer than 90 per cent of the control chickens die or show severe clinical signs of avian infectious laryngotracheitis or notable macroscopic lesions of the trachea and orbital sinuses,
- or if during the period between the vaccination and challenge more than 10 per cent of the vaccinated or control chickens show notable clinical signs of disease or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not fewer than 90 per cent of the vaccinated chickens survive and show no notable clinical signs of disease and/or macroscopical lesions of the trachea and orbital sinuses.

3. BATCH TESTS

3-1. Identification. The vaccine, diluted if necessary and mixed with a monospecific infectious laryngotracheitis virus antiserum, no longer infects embryonated hens' eggs from an SPF flock (5.2.2) or susceptible cell cultures (5.2.4) into which it is inoculated.

3-2. Bacteria and fungi

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062).

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062) or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for micro-organisms detected in the vaccine; the vaccine does not contain pathogenic micro-organisms and contains not more than 1 non-pathogenic micro-organism per dose.

Any liquid supplied with the vaccine complies with test for sterility in the monograph *Vaccines for veterinary use* (0062).

3-3. Mycoplasmas. The vaccine complies with the test for mycoplasmas (2.6.7).

3-4. Extraneous agents. The vaccine complies with the tests for extraneous agents in batches of finished product (2.6.25).

3-5. Safety. Use not fewer than 10 chickens from an SPF flock (5.2.2) and of the youngest age recommended for vaccination. Administer by eye-drop to each chicken 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. Virus titre. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (5.2.2) or into suitable cell cultures (5.2.4). The vaccine complies with the test if 1 dose contains not less than the minimum titre stated on the label.

3-7. Potency. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-4-4) when administered according to the recommended schedule by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

AVIAN PARAMYXOVIRUS 3 VACCINE (INACTIVATED)

Vaccinum paramyxoviris 3 aviarii inactivatum

DEFINITION

Avian paramyxovirus 3 vaccine (inactivated) consists of an emulsion or a suspension of a suitable strain of avian paramyxovirus 3 that has been inactivated in such a manner that immunogenic activity is retained. The vaccine is used for protection against loss in egg production and egg quality in turkeys.

PRODUCTION

The virus is propagated in embryonated eggs from healthy flocks or in suitable cell cultures (5.2.4).

The test for inactivation is carried out in embryonated eggs or suitable cell cultures and the quantity of inactivated virus used is equivalent to not less than ten doses of vaccine. No live virus is detected.

The vaccine may contain an adjuvant.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and immunogenicity (5.2.7) for each category of turkeys for which it is intended. The following test may be used during demonstration of immunogenicity.

Immunogenicity. The test described under Potency is suitable for demonstrating immunogenicity.

BATCH TESTING

Batch potency test. Carry out a suitable validated test for which satisfactory correlation with the test described under Potency has been established, the criteria for acceptance being set with reference to a batch that has given satisfactory results in the latter test.

IDENTIFICATION

When injected into animals free from antibodies against avian paramyxovirus 3, the vaccine stimulates the production of such antibodies.

TESTS

Safety. Inject twice the vaccinating dose by a recommended route into each of ten turkeys, 14 to 28 days old and free from antibodies against avian paramyxovirus 3. Observe the birds for 21 days. No abnormal local or systemic reaction occurs.

Inactivation. Inject two-fifths of a dose into the allantoic cavity of each of ten embryonated hen eggs, 9 to 11 days old, from flocks free from specified pathogens (5.2.2) (SPF eggs) and incubate. Observe for 6 days and pool separately the allantoic fluid from eggs containing live embryos, and that from eggs containing dead embryos, excluding those dying within 24 h of the injection. Examine embryos that die within 24 h of injection for the presence of avian paramyxovirus 3: the vaccine does not comply with the test if avian paramyxovirus 3 is found.

Inject into the allantoic cavity of each of ten SPF eggs, 9 to 11 days old, 0.2 ml of the pooled allantoic fluid from the live embryos and, into each of ten similar eggs, 0.2 ml of the pooled fluid from the dead embryos and incubate for 5 to 6 days. Test the allantoic fluid from each egg for the presence of haemagglutinins using chicken erythrocytes.

The vaccine complies with the test if there is no evidence of haemagglutinating activity and if not more than 20 per cent of the embryos die at either stage. If more than 20 per cent of the embryos die at one of the stages, repeat that stage; the vaccine complies with the test if there is no evidence of haemagglutinating activity and not more than 20 per cent of the embryos die at that stage.

Antibiotics may be used in the test to control extraneous bacterial infection.

Extraneous agents. Inject a double dose by a recommended route into each of ten chickens, 14 to 28 days old and from a flock free from specified pathogens (5.2.2). After 3 weeks, inject one dose by the same route. Collect serum samples from each chicken 2 weeks later and carry out tests for antibodies against the following agents by the methods prescribed for chicken flocks free from specified pathogens (5.2.2): avian encephalomyelitis virus, avian infectious bronchitis virus, avian leucosis viruses, egg-drop syndrome virus, avian bursal disease virus, avian infectious laryngotracheitis virus, influenza A virus, Marek's disease virus. The vaccine does not stimulate the formation of antibodies against these agents.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Use two groups each of not fewer than twenty turkeys free from antibodies against avian paramyxovirus 3. Vaccinate one group in accordance with the recommendations for use. Keep the other group as controls. The test is invalid if serological tests carried out on serum samples obtained at the time of first vaccination show the presence of antibodies against avian paramyxovirus 3 in either vaccinates or controls or if tests carried out at the time of challenge show such antibodies in controls. At the egg-production peak, challenge the two groups by the oculo-nasal route with a sufficient quantity of a virulent strain of avian paramyxovirus 3. For not less than 6 weeks after challenge, record the number of eggs laid weekly for each group, distinguishing between normal and abnormal eggs. The vaccine complies with the test if egg production and quality are significantly better in the vaccinated group than in the control group.

01/2005:1956

AVIAN VIRAL TENOSYNOVITIS VACCINE (LIVE)

Vaccinum tenosynovitis viralis aviariae vivum

1. DEFINITION

Avian viral tenosynovitis vaccine (live) is a preparation of a suitable strain of avian tenosynovitis virus (avian orthoreovirus). This monograph applies to vaccines intended for administration to chickens for active immunisation.

2. PRODUCTION

2-1. PREPARATION OF THE VACCINE

The vaccine virus is grown in cell cultures.

2-2. SUBSTRATE FOR VIRUS PROPAGATION

2-2-1. Cell cultures. Cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (5.2.4).

2-3. SEED LOTS

2-3-1. Extraneous agents. The master seed lot complies with the tests for extraneous agents in seed lots (2.6.24). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. CHOICE OF VACCINE VIRUS

The vaccine virus shall be shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during the demonstration of safety and immunogenicity.

2-4-1. Safety. Carry out the test for each route and method of administration to be recommended for vaccination using in each case chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test use not fewer than 20 chickens, from an SPF flock (5.2.2). Administer to each chicken a quantity of the vaccine virus not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Observe the chickens at least daily for 21 days. Carry out histological examination of the joints and tendon sheaths of the legs and feet at the end of the observation period (as a basis for comparison in the test for increase in virulence). The test is not valid if more than 10 per cent of the chickens die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no chicken shows notable clinical signs of avian viral tenosynovitis or dies from causes attributable to the vaccine virus.

2-4-2. Increase in virulence. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to a group of five 1-day-old chicks from an SPF flock (5.2.2), sequential passages, 5 times where possible, to further groups of 1-day-old chicks and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by a suitable route a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Kill the chickens at the moment when the virus concentration in the most suitable material (for example, tendons, tendon sheaths and liquid exudates from the hock joints, spleen) is sufficient. Prepare a suspension from this material from each chicken and pool these samples. Administer 0.1 ml of the pooled samples by the route of administration most likely to lead to increase in virulence to each of 5 other chickens of the same age and origin. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for safety (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged vaccine virus that has been recovered. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If the virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. **Immunogenicity.** A test is carried out for each route and method of administration to be recommended using in each case chickens not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each chicken is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. Use not fewer than 30 chickens of the same origin and from an SPF flock (5.2.2). Administer the vaccine by a recommended route to not fewer than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 21 days by a suitable route with a sufficient quantity of virulent avian tenosynovitis virus. Observe the chickens at least daily for 21 days after challenge. Record the deaths and the surviving chickens that show clinical signs of disease. If the challenge is administered by the foot pad, any transient swelling of the foot pad during the first 5 days after challenge may be considered non-specific. At the end of the observation period, kill all the surviving chickens and carry out macroscopic and/or microscopic examination for lesions of the joints and tendon sheaths of the legs and feet, e.g. exudate and swelling. The test is not valid if:

- during the observation period after challenge fewer than 80 per cent of the control chickens die or show severe clinical signs of avian viral tenosynovitis or show macroscopical and/or microscopical lesions in the joints and tendon sheaths of the legs and feet,
- or if during the period between vaccination and challenge more than 10 per cent of the control or vaccinated chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not fewer than 90 per cent of the vaccinated chickens survive and show no notable clinical signs of disease or show macroscopical and/or microscopical lesions in the joints and tendon sheaths of the legs and feet.

3. BATCH TESTS

3-1. **Identification.** Carry out an immunostaining test in cell cultures to identify the vaccine virus.

3-2. Bacteria and fungi

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062).

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062) or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062).

3-3. **Mycoplasmas.** The vaccine complies with the test for mycoplasmas (2.6.7).

3-4. **Extraneous agents.** The vaccine complies with the tests for extraneous agents in batches of finished product (2.6.25).

3-5. **Safety.** Use not fewer than 10 chickens from an SPF flock (5.2.2) and of the youngest age recommended for vaccination. Administer by a recommended route and method to each chicken 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal

clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre.** Titrate the vaccine virus by inoculation into suitable cell cultures (5.2.4). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency.** The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-4-3) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2005:1939

BOVINE LEPTOSPIROSIS VACCINE (INACTIVATED)

Vaccinum leptospirosis bovine inactivatum

DEFINITION

Bovine leptospirosis vaccine (inactivated) is a suspension of inactivated whole organisms and/or antigenic extract(s) of one or more suitable strains of one or more of *Leptospira borgpetersenii* serovar hardjo, *Leptospira interrogans* serovar hardjo or other *L. interrogans* serovars, inactivated and prepared in such a way that adequate immunogenicity is maintained. This monograph applies to vaccines intended for active immunisation of cattle against leptospirosis.

PRODUCTION

The seed material is cultured in a suitable medium; each strain is cultivated separately. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity are verified on the harvest using suitable methods. After cultivation, the bacterial harvest is inactivated by a suitable method. The antigen may be concentrated. The vaccine may contain an adjuvant.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) in cattle. As part of the studies to demonstrate the suitability of the vaccine with respect to these characteristics the following tests may be carried out.

Safety

A. The test is carried out for each route of administration to be stated on the label and in animals of each category (for example, young calves, pregnant cattle) for which the vaccine is intended. For each test, use not fewer than 10 animals that do not have antibodies against *L. borgpetersenii* serovar hardjo and the principal serovars of *L. interrogans* (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis). Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine. Administer to each animal a double dose of vaccine. If the recommended schedule requires a second dose, administer 1 dose after the recommended interval. Observe the animals for at least 14 days after the last administration. Record body temperatures the day before each vaccination, at vaccination, 4 h later and daily for 4 days. If the vaccine is intended for use or may be used in pregnant cattle,

vaccinate the animals at the relevant stages of pregnancy and prolong the observation period until 1 day after calving. The vaccine complies with the test if no animal shows an abnormal local or systemic reaction or clinical signs of disease or dies from a cause attributable to the vaccine. In addition, if the vaccine is for use in pregnant animals, no adverse effects on the pregnancy and offspring are noted.

- B. The animals used for the field trials are also used to evaluate safety. Use not fewer than 3 groups of 20 animals with corresponding groups of not fewer than 10 controls in 3 different locations. Examine the injection sites for local reactions after vaccination. Record body temperatures the day before vaccination, at vaccination and on the 2 days following vaccination. The vaccine complies with the test if no animal shows an abnormal local or systemic reaction or clinical signs of disease or dies from a cause attributable to the vaccine. In addition, if the vaccine is for use in pregnant animals, no adverse effects on the pregnancy and offspring are noted.

Immunogenicity. As part of the studies to demonstrate the suitability of the vaccine with respect to immunogenicity and in support of the claims for a beneficial effect on the rates of infection and urinary excretion, the test described under Potency may be carried out for each proposed route of administration, using vaccine of minimum potency. Urine samples are collected from each animal on days 0, 14, 21, 28 and 35 post-challenge. For leptospiral species other than *L. borgpetersenii* serovar hardjo, appropriate days are determined by the characteristics of the challenge model. In the case of other serovars for which there is published evidence that the serovar has a lower tropism for the urinary tract, a lower rate of infection may be justified. Depending on their tissue tropism, for some leptospira serovars, samples from other tissues/body fluids can be used to establish whether the animals are infected or not by the challenge organism. If claims are to be made for protection against reproductive or production losses, further specific studies will be required.

BATCH POTENCY TEST

The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a suitable correlation with the test described under Potency has been established.

For each of the serovars for which protection is claimed, the antibody response from vaccinated animals is measured. Use guinea pigs weighing 250-350 g which do not have antibodies to *L. borgpetersenii* serovar hardjo and the principal serovars of *L. interrogans* (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis) and which have been obtained from a regularly tested and certified leptospira-free source. The dose to be administered to the animals is that fraction of a cattle dose which has been shown in the validation studies to provide a suitably sensitive test. Vaccinate each of 10 animals with the suitable dose. Maintain not fewer than 2 guinea-pigs as unvaccinated controls. At a given interval within the range of 19 to 23 days after the injection, collect blood from each animal and prepare serum samples. Use a suitable validated method such as a micro-agglutination test to measure the antibody responses in each sample. The

antibody levels are equal to or greater than those obtained with a batch that has given satisfactory results in the test described under Potency and there is no significant increase in antibody titre in the controls.

IDENTIFICATION

When injected into healthy seronegative animals, the vaccine stimulates the production of specific antibodies to the leptospira serovar(s) present in the vaccine.

TESTS

Safety. For vaccines recommended for use in cattle older than 6 months of age, use cattle not older than the minimum age recommended for vaccination and not younger than 6 months of age. For vaccines recommended for use in cattle less than 6 months of age, use cattle of the minimum age recommended for vaccination. Inject 2 doses of the vaccine into each of 2 cattle, free from specific antibodies to the leptospira serovar(s) present in the vaccine, by a recommended route. Observe the animals for 14 days. The animals remain in good health and no abnormal local or systemic reaction occurs.

Inactivation. Carry out a test for live leptospirae by inoculation of a specific medium. Inoculate 1 ml of the vaccine into 100 ml of the medium. Incubate at 30 °C for 14 days, subculture into a further quantity of the medium and incubate both media at 30 °C for 14 days: no growth occurs in either medium. At the same time, carry out a control test by inoculating a further quantity of the medium with the vaccine together with a quantity of a culture containing approximately 100 leptospirae and incubating at 30 °C: growth of leptospirae occurs within 14 days.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062).

POTENCY

Carry out a separate test for each of the serovars for which a claim is made for a beneficial effect on the rates of infection and urinary excretion.

Use not fewer than 15 cattle of the minimum age recommended for vaccination and free from specific antibodies against *L. borgpetersenii* serovar hardjo and the principal serovars of *L. interrogans* (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis). Vaccinate not fewer than 10 animals by a recommended route and according to the recommended schedule. Keep not fewer than 5 animals as controls. 21 days after the last vaccination, infect all the animals by a suitable mucosal route with a suitable quantity of a virulent strain of the relevant serovar. Observe the animals for a further 35 days. Collect urine samples from each animal on days 0, 14, 21, 28 and 35 post-challenge. Kill surviving animals at the end of the observation period. Carry out post-mortem examination on any animal that dies and on those killed at the end of the observation period. In particular, examine the kidneys for macroscopic and microscopic signs of leptospira infection. A sample of each kidney is collected and each urine and kidney sample is tested for the presence of the challenge organisms by re-isolation or by another suitable method.

For the test conducted with *L. borgpetersenii* serovar hardjo, control animals are regarded as infected if the challenge organisms are re-isolated from at least 2 samples. The test is invalid if infection has been established in fewer than 80 per cent of the control animals.

The vaccine complies with the requirements of the test if the challenge organisms are re-isolated from any urine or kidney sample from not more than 20 per cent of the vaccinated animals.

LABELLING

The label states:

- the serovar(s) used to prepare the vaccine,
- the serovar(s) against which protection is claimed.

01/2005:1176

BOVINE PARAINFLUENZA VIRUS VACCINE (LIVE), FREEZE-DRIED

Vaccinum parainfluenzae viri bovini vivum cryodesiccatum

DEFINITION

Freeze-dried bovine parainfluenza virus vaccine (live) is a preparation of a suitable strain of bovine parainfluenza 3 virus.

PRODUCTION

The vaccine strain is grown in suitable cell cultures (5.2.4). The viral suspension is harvested, mixed with a suitable stabilising liquid and freeze-dried.

CHOICE OF VACCINE STRAIN

Only a virus strain shown to be satisfactory with respect to reversion to virulence, safety and immunogenicity may be used in the preparation of the vaccine. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Reversion to virulence. Administer by the intranasal route to 2 susceptible calves that do not have antibodies against bovine parainfluenza virus 3 a quantity of virus that will allow optimal re-isolation of the virus for subsequent passages. On each of days 3 to 7 after administration of the virus, take nasal swabs from each calf and collect in not more than 5 ml of a suitable medium which is then used to inoculate cell cultures to verify the presence of virus; use about 1 ml of the suspensions from swabs that contain the maximum amount of virus, as indicated by the titration in cell cultures, to inoculate 2 other calves of the same age and sensitivity; repeat these operations until 5 passages on calves have been carried out. No calf shows clinical signs attributable to the vaccinal virus. No indication of increase of virulence, compared to the original vaccinal virus is observed; account is taken of the titre of excreted virus in the nasal swabs.

Safety. The test is carried out for each recommended route of administration. Use calves of the minimum age recommended for vaccination and preferably having no antibodies against bovine parainfluenza 3 virus or, where justified, use calves with a very low level of such antibodies as long as they have not been vaccinated against bovine parainfluenza virus and administration of the vaccine does not cause an anamnestic response. Administer to 5 calves a quantity of virus corresponding to not less than 10 times the maximum virus titre that may be expected in a batch of vaccine. Observe the animals for 21 days. Measure the body temperature of each animal on the day before vaccination, at the time of vaccination and for the 4 subsequent days. No abnormal effect on body temperature and no abnormal local or systemic reactions occur.

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity of the vaccine strain.

BATCH TESTING

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot, subject to agreement by the competent authority.

IDENTIFICATION

Carry out an immunofluorescence test in suitable cell cultures, using a monospecific antiserum.

TESTS

Safety. Use calves of the minimum age recommended for vaccination and preferably having no antibodies against bovine parainfluenza 3 virus or, where justified, use calves with a very low level of such antibodies as long as they have not been vaccinated against bovine parainfluenza virus and administration of the vaccine does not cause an anamnestic response. Administer 10 doses of the vaccine by a recommended route to each of 2 calves. Observe the animals for 21 days. No abnormal local or systemic reaction occurs.

Extraneous viruses. Neutralise the vaccine using a monospecific antiserum against bovine parainfluenza 3 virus and inoculate into cell cultures known to be sensitive to viruses pathogenic for cattle. Maintain these cultures for 14 days and make at least one passage during this period. No cytopathic effect develops; the cells show no evidence of the presence of haemadsorbing agents. Carry out a specific test for pestiviruses.

Bacterial and fungal contamination. The vaccine complies with the test for sterility prescribed under *Vaccines for veterinary use (0062)*.

Mycoplasmas (2.6.7). The vaccine complies with the test for mycoplasmas.

Virus titre. Titrate the vaccine in suitable cell cultures. One dose of the vaccine contains not less than the quantity of virus equivalent to the minimum virus titre stated on the label.

POTENCY

Use not fewer than 10 calves of the minimum age recommended for vaccination and that do not have antibodies against bovine parainfluenza 3 virus; calves having low levels of such antibodies may be used if it has been demonstrated that valid results are obtained in these conditions. Collect sera from the animals before vaccination, 7 days and 14 days after the time of vaccination and just before challenge. Vaccinate not fewer than 5 of the calves according to the instructions for use. Keep 5 calves as controls. Observe the animals for 21 days and then administer to each of them by a respiratory tract route a suitable quantity of a low-passage virulent strain of bovine parainfluenza 3 virus. Monitor each animal for clinical signs, in particular respiratory symptoms, and virus shedding (by nasal swabs or tracheobronchial washing) for 14 days after challenge. The vaccine complies with the test if in vaccinated animals compared to controls there is (a) a significant reduction in mean titre and in mean duration of virus excretion and (b) a notable reduction in general and local signs (if the challenge virus used produces such signs). The test is not valid if tests for antibodies against bovine parainfluenza 3 virus on the sera indicate that there was intercurrent infection with the virus during the test or if

more than 2 of the 5 control animals show no excretion of the challenge virus, as shown by nasal swabs or samples harvested by tracheobronchial washing.

vaccine or to wild virus. The vaccine is satisfactory if it is not associated with an abnormal incidence of immediate hypersensitivity reactions.

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity of the vaccine strain.

01/2005:1177

BOVINE RESPIRATORY SYNCYTIAL VIRUS VACCINE (LIVE), FREEZE-DRIED

*Vaccinum viri syncytialis meatus spiritus
bovini vivum cryodesiccatum*

DEFINITION

Freeze-dried bovine respiratory syncytial virus vaccine (live) is a preparation of a suitable strain of bovine respiratory syncytial virus.

PRODUCTION

The vaccine strain is grown in suitable cell cultures (5.2.4). The viral suspension is harvested, mixed with a suitable stabilising solution and freeze-dried.

CHOICE OF VACCINE STRAIN

Only a virus strain shown to be satisfactory with respect to reversion to virulence, safety and immunogenicity may be used in the preparation of the vaccine. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Reversion to virulence. Administer by the intranasal route to two susceptible calves that do not have antibodies against bovine respiratory syncytial virus a quantity of virus that will allow optimal re-isolation of the virus for subsequent passages. On each of days 3 to 7 after administration of the virus, take nasal swabs from each calf and collect in not more than 5 ml of a suitable medium which is then used to inoculate cell cultures to verify the presence of virus; use about 1 ml of the suspensions from swabs that contain the maximum amount of virus, as indicated by the titration in cell cultures, to inoculate two other calves of the same age and sensitivity; repeat these operations until five passages on calves have been carried out. No calf shows clinical signs attributable to the vaccinal virus. No indication of increase of virulence compared to the original vaccinal virus is observed; account is taken of the titre of excreted virus in the nasal swabs.

Safety. Safety studies are conducted in calves of the minimum age for which the vaccine is recommended and for each recommended route of administration.

- A. Administer by a recommended route to five calves, without antibodies against bovine respiratory syncytial virus, a quantity of virus corresponding to not less than ten times the maximum virus titre that may be expected in a batch of vaccine. Observe the animals for 21 days. Measure the rectal temperature of each animal on the day before vaccination, at the time of vaccination and daily for the following 7 days. No abnormal effect on body temperature and no abnormal local or systemic reaction are noted.
- B. The animals used for the field trials are also used to evaluate the incidence of hypersensitivity reactions in vaccinated animals following subsequent exposure to the

BATCH TESTING

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot, subject to agreement by the competent authority.

IDENTIFICATION

Identify the vaccine by an immunofluorescence test in suitable cell cultures using a monospecific antiserum.

TESTS

Safety. Administer ten doses of the vaccine by a recommended route to each of two calves of the minimum age recommended for vaccination and that do not have antibodies against bovine respiratory syncytial virus. Observe the animals for 21 days. No abnormal local or systemic reaction occurs.

Extraneous viruses. Neutralise the vaccine using a monospecific antiserum against bovine respiratory syncytial virus and inoculate into cell cultures known to be sensitive to viruses pathogenic for cattle. Maintain the cultures for 14 days and make at least one passage during this period. No cytopathic effect develops; the cells show no evidence of the presence of haemadsorbing agents. Carry out a specific test for pestiviruses.

Bacterial and fungal contamination. The vaccine complies with the test for sterility prescribed under *Vaccines for veterinary use (0062)*.

Mycoplasmas (2.6.7). The vaccine complies with the test for mycoplasmas.

Virus titre. Titrate the vaccine in suitable cell cultures. One dose of the vaccine contains not less than the quantity of virus equivalent to the minimum titre stated on the label.

POTENCY

Use not fewer than ten calves of the minimum age recommended for vaccination and that do not have antibodies against bovine respiratory syncytial virus. Collect sera from the animals before the time of vaccination, 7 and 14 days after the time of vaccination and just before challenge. Vaccinate not fewer than five of the calves according to the instructions for use. Keep five calves as controls. Observe the animals for 21 days and then administer to each of them by a respiratory tract route a suitable quantity of a low-passage virulent strain of bovine respiratory syncytial virus. Monitor each animal for clinical signs, in particular respiratory symptoms, and virus shedding (by nasal swabs or tracheobronchial washing) for 14 days after challenge. The vaccine complies with the test if there is: (a) a significant reduction in mean titre and in mean duration of virus excretion in vaccinates compared to controls and (b) a notable reduction in general and local clinical signs in vaccinated animals (if the challenge virus used produces such signs). The test is not valid if antibodies to bovine respiratory syncytial virus are detected in any sample from control animals before challenge or if more than two of the five control animals show no excretion of the challenge virus, as shown by nasal swabs or samples harvested by tracheobronchial washing.

01/2005:1952

BOVINE VIRAL DIARRHOEA VACCINE (INACTIVATED)

Vaccinum diarrhoeae viralis bovinæ inactivatum

DEFINITION

Bovine viral diarrhoea vaccine (inactivated) is a preparation of one or more suitable strains of bovine diarrhoea virus inactivated by a suitable method. This monograph applies to vaccines intended for vaccination of heifers and cows to protect the foetus against transplacental infection.

PRODUCTION

The vaccine virus strain or strains are grown in suitable cell cultures (5.2.4).

The test for inactivation is carried out using a quantity of virus equivalent to not less than 25 doses of vaccine in cells of the same type as those used for production of the vaccine or cells shown to be at least as sensitive; the cells are passaged after 7 days and observed for a total of not less than 14 days. No infectious virus is detected.

CHOICE OF VACCINE COMPOSITION

The vaccine shall be shown to be satisfactory with respect to safety (5.2.6) and immunogenicity (5.2.7) in cattle.

The following tests may be used during the demonstration of safety and immunogenicity.

Safety. Carry out a safety test for each recommended route and for each category of cattle for which the vaccine is intended. Use cattle of the minimum age recommended for vaccination and that are free from bovine diarrhoea virus and from antibodies against the virus. Inject a double dose of vaccine into each of not fewer than 10 animals. Observe the animals for 14 days. No abnormal local or systemic reaction occurs. If the vaccine is intended for administration to pregnant cattle, carry out the test in these animals at the beginning of each trimester for which use is not contra-indicated and extend the observation period to calving. No undesirable effect on gestation or the offspring occurs. If the vaccine is intended for administration shortly before or at insemination, absence of undesirable effects on conception rate must be demonstrated.

Immunogenicity. The test for potency is suitable to demonstrate the immunogenicity of the vaccine with respect to bovine diarrhoea virus of genotype 1; if protection against bovine diarrhoea virus of genotype 2 is claimed, an additional test, similar to that described under Potency, but using bovine diarrhoea virus of genotype 2 for challenge, is carried out.

BATCH POTENCY TEST

The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out for a given vaccine on one or more occasions as decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Inject subcutaneously a suitable dose of the vaccine into each of 5 suitable seronegative laboratory animals or calves. Keep 2 animals as controls. A second dose of vaccine may be administered after a suitable interval if this has been shown

to provide a suitably discriminating test system. Collect blood samples before the first vaccination and at a given interval between 14 and 21 days after the last vaccination. Determine the antibody titres against bovine diarrhoea virus by seroneutralisation on suitable cell cultures. The test is invalid if the control animals show antibodies against bovine diarrhoea virus. The vaccine complies with the test if the level of antibodies is not lower than that found for a batch of vaccine that has given satisfactory results in the test described under Potency.

IDENTIFICATION

When administered to animals free from specific neutralising antibodies against bovine diarrhoea virus, the vaccine stimulates the production of such antibodies.

TESTS

Safety. Inject a double dose of the vaccine by a recommended route into each of 2 cattle not older than the minimum age recommended for vaccination and that are free from bovine diarrhoea virus and antibodies against the virus. Observe the animals for 14 days. No abnormal local or systemic reaction occurs.

Inactivation. Carry out a test for residual infectious bovine diarrhoea virus by inoculating not less than 10 doses onto cells known to be sensitive to bovine diarrhoea virus; passage the cells after 7 days and observe the second culture for not less than 7 days. No live virus is detected. If the vaccine contains an adjuvant, separate the adjuvant if possible from the liquid phase by a method that does not interfere with the detection of possible live virus.

Bacteria and fungi. The vaccine complies with the requirement for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

POTENCY

Use heifers free from bovine diarrhoea virus that do not have neutralising antibodies against bovine diarrhoea virus. Vaccinate not fewer than 13 animals using the recommended schedule. Keep not fewer than 7 heifers as non-vaccinated controls. Keep all the animals as one group. Inseminate the heifers. Take a blood sample from non-vaccinated heifers shortly before challenge. The test is discontinued if fewer than 10 vaccinated heifers or 5 non-vaccinated heifers are pregnant at the time of challenge. Between the 60th and 90th days of gestation, challenge the animals. For both test models described (observation until calving and harvest of foetuses at 28 days), challenge may be made by the intranasal inoculation of a suitable quantity of a non-cytopathic strain of bovine diarrhoea virus or alternatively, where the animals are observed until calving, challenge may be made by contact with a persistently viraemic animal. Observe the animals clinically from challenge either until the end of gestation or until harvest of foetuses after 28 days. If abortion occurs, examine the aborted foetus for bovine diarrhoea virus by suitable methods. If animals are observed until calving, immediately after birth and prior to ingestion of colostrum, examine all calves for viraemia and antibodies against bovine diarrhoea virus. If foetuses are harvested 28 days after challenge, examine the foetuses for bovine diarrhoea virus by suitable methods. Transplacental infection is considered to have occurred if virus is detected in foetal organs or in the blood of newborn calves or if antibodies are detected in precolostral sera of calves. The test is invalid if any of the non-vaccinated heifers have neutralising antibody before challenge or if transplacental infection fails to occur in more than 10 per cent of non-vaccinated heifers. The vaccine complies with the test if 90 per cent or more of the vaccinated animals are protected from transplacental infection.

01/2005 :0793

BRUCELLOSIS VACCINE (LIVE) (BRUCELLA MELITENSIS REV. 1 STRAIN), FREEZE-DRIED, FOR VETERINARY USE

Vaccinum brucellosis (*Brucella melitensis*
stirpe Rev. 1) vivum cryodesiccatum
ad usum veterinarium

DEFINITION

Brucellosis vaccine (live) (*Brucella melitensis* Rev. 1 strain), freeze-dried, for veterinary use is a freeze-dried suspension of live *Brucella melitensis* Rev. 1 strain. The vaccine contains not fewer than 0.5×10^9 and not more than 4×10^9 live bacteria per dose.

PRODUCTION

Brucella melitensis Rev. 1 strain is cultured in a suitable medium. The method of culture is such as to avoid bacterial dissociation and thus maintain the smooth characteristic of the culture. The bacteria are suspended in a buffer solution which may contain a suitable stabiliser. The suspension is distributed into containers and freeze-dried.

CHOICE OF VACCINE STRAIN

Only a vaccine strain shown to be satisfactory with respect to safety and immunogenicity may be used in the production of the vaccine. The following test may be used during demonstration of efficacy (5.2.7).

Immunogenicity. 40 ewe lambs, 4 to 5 months old, from a non-vaccinated flock free from brucellosis are used. For the challenge strain, a 24-hour culture of *Brucella melitensis* strain H38 in trypticase agar is used. A preliminary test using animals of the same breed and age as for the main test is carried out to determine the challenge dose, which is between 10^7 and 10^8 colony-forming units and is chosen so as to produce abortion in all non-vaccinated animals. Half the animals are vaccinated at 4 to 6 months of age, according to the recommended schedule and using the minimum recommended dose. Oestrus is synchronised in the 40 animals which are then inseminated at 10 to 12 months of age. A diagnosis of pregnancy is made on all animals 2 to 3 months after insemination and all non-gravid animals are excluded from the test. All gravid animals are challenged by conjunctival instillation of the challenge dose of *Brucella melitensis* strain H38. The occurrence of abortion is noted and aetiology confirmed by testing for the presence of the challenge strain in the aborted foetus and in the ewe (using selective media of Kuzdas and Morse or of Farrell). Tests for the presence of the challenge strain are carried out on each animal at lambing. Tests for the presence of the challenge strain in the prescapular and retromammary lymph nodes are carried out at slaughter of the animals 4 to 6 weeks after lambing. The test is not valid unless at least 70 per cent of non-vaccinated animals: show abortion caused by the challenge strain; show infection with the challenge strain at lambing; show infection of the prescapular and retromammary lymph nodes at slaughter. The vaccine complies with the test if: not more than 30 per cent of vaccinated animals show abortion caused by the challenge strain; the challenge strain is found in not more than 50 per

cent of vaccinated animals at lambing; the challenge strain is found in not more than 40 per cent of vaccinated animals at slaughter.

IDENTIFICATION

Brucella melitensis present in the vaccine is identified by suitable morphological, serological and biochemical tests and by culture: Rev. 1 strain is inhibited by addition to the suitable culture medium of 3 µg of benzylpenicillin sodium per millilitre; the strain grows on agar containing 2.5 µg of streptomycin per millilitre.

TESTS

Safety. Use 2 sheep, 4 to 6 months old and having no antibodies against *B. melitensis*. Administer 1 dose of vaccine by a recommended route to each sheep. Observe the animals for 21 days. No abnormal local or systemic reaction occurs.

Determination of dissociation phase. Examine not fewer than 200 colonies by a suitable technique. The culture of the vaccine strain is seen to be in the smooth (S) phase. Not fewer than 95 per cent of the colonies are of the smooth type.

Extraneous micro-organisms. The reconstituted vaccine does not contain extraneous micro-organisms. Verify the absence of micro-organisms other than *Brucella melitensis* Rev. 1 strain as described in the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

Live bacteria. Make a count of live bacteria on a solid medium suitable for the culture of *Brucella melitensis* Rev. 1 strain. The vaccine contains not fewer than 0.5×10^9 and not more than 4×10^9 live bacteria per dose.

Fifty per cent persistence time. Inject subcutaneously a suspension containing 10^8 live bacteria of the vaccine to be examined into each of 32 female CD1 mice, aged 5 to 6 weeks. Kill the mice in groups of eight, selected at random, 3, 6, 9 and 12 weeks later. Remove the spleens and homogenise individually and aseptically in 10 volumes of *phosphate buffered saline pH 6.8 R*. Spread the suspension on plates containing a suitable culture medium, using 0.4 ml per plate and not fewer than 3 plates per spleen (lower limit of detection: 5 bacteria per spleen). Carry out in parallel a similar test using *Brucella melitensis* Rev. 1 strain BRP (reference strain). Calculate the 50 per cent persistence time by the usual statistical methods (5.3) for probit analysis. The 50 per cent persistence time for the vaccine strain does not differ significantly from that of the reference strain. For Rev. 1 strain, the 50 per cent persistence time and confidence limits ($P = 0.05$) are usually 7.9 ± 1.2 weeks.

STORAGE

Store at a temperature of 2 °C to 8 °C.

LABELLING

The label states:

- the number of *Brucella melitensis* Rev. 1 strain per dose,
- that the vaccine is intended for sheep and goats 4 to 6 months old,
- that the vaccine may be dangerous for man,
- that the vaccine is not to be used in pregnant or lactating animals,
- that the vaccine may be dangerous for cattle and that they are not to be kept in contact with vaccinated animals.

01/2005:1953

CALF CORONAVIRUS DIARRHOEA VACCINE (INACTIVATED)

Vaccinum inactivatum diarrhoeae vituli coronaviro illatae

DEFINITION

Calf coronavirus diarrhoea vaccine (inactivated) is a preparation of one or more suitable strains of bovine coronavirus, inactivated in such a manner that immunogenic properties are maintained. The vaccine is administered to the dam to aid in the control of coronavirus diarrhoea in offspring during the first few weeks of life.

PRODUCTION

Each virus strain is grown separately in suitable cell cultures (5.2.4). The viral suspensions of each strain are harvested separately and inactivated by a method that maintains immunogenicity. The viral suspensions may be purified and concentrated.

The test for inactivation is carried out using 2 passages in cell cultures of the same type as those used for production or in cells shown to be at least as sensitive. The quantity of virus used in the test is equivalent to not less than 10 doses of vaccine. No live virus is detected.

The vaccine may contain an adjuvant.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) in the pregnant cow. The following tests may be used during demonstration of safety and immunogenicity.

Safety. Carry out the test for each proposed route of administration. Administer by a proposed route and at the proposed stage or stages of pregnancy, a double dose of vaccine to each of not fewer than 10 pregnant cows that have not been vaccinated against bovine coronavirus. After the proposed interval, inject 1 dose into each cow. After each injection, measure the body temperature on the day of the injection and on the 4 following days. Observe the cows until calving. No abnormal local or systemic reaction occurs; any effects on gestation and the offspring are noted.

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity of the strain.

BATCH TESTING

Batch potency test. The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a suitable correlation with the test described under Potency has been established.

To obtain a valid assay, it may be necessary to carry out a test using several groups of animals, each receiving a different dose. For each dose required, carry out the test as follows. Vaccinate not fewer than 5 animals of a suitable species, free from specific antibodies against bovine coronavirus, using 1 injection of a suitable dose. Maintain not fewer than 2 animals as unvaccinated controls. Where the recommended schedule requires a booster injection to be given, a booster vaccination may also be given in this test

provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval not less than 14 days after the last injection, collect blood from each animal and prepare serum samples. Use a suitable validated test to measure the antibody response. The antibody level is not significantly less than that obtained with a batch that has given satisfactory results in the test described under Potency and there is no significant increase in antibody titre in the controls.

IDENTIFICATION

Injected into animals free from specific antibodies against bovine coronavirus, the vaccine stimulates the formation of such antibodies.

TESTS

Safety. Use cattle not less than 6 months old and preferably having no antibodies against bovine coronavirus or, where justified, use cattle with a low level of such antibodies as long as they have not been vaccinated against bovine coronavirus and administration of the vaccine does not cause an anamnestic response. Administer to each of 2 animals a double dose of vaccine by a recommended route. After 14 days, administer 1 dose to each animal. Observe the animals for 14 days. No abnormal local or systemic reaction occurs.

Inactivation. Carry out a test for residual infectious virus using 10 doses of vaccine and 2 passages in cell cultures of the same type as those used for production of the vaccine or other cell cultures of suitable sensitivity. No live virus is detected. If the vaccine contains an adjuvant which interferes with the test, separate it if possible from the liquid phase of the vaccine by a method that does not inactivate virus nor interfere in any other way with detection of live viruses.

Extraneous viruses. Carry out tests for antibodies on the cattle used for the safety test. Take a blood sample at the end of the second observation period. The vaccine does not stimulate the formation of antibodies against bovine herpes virus 1 (BHV1), bovine leukaemia virus (BLV) and bovine viral diarrhoea virus (BVDV).

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Use not fewer than 15 pregnant cows, where possible having no antibodies against bovine coronavirus. Where such cows are not available, use cows that: have not been vaccinated against bovine coronavirus; come from a farm where there is no recent history of infection with bovine coronavirus; and have a low level of antibodies against bovine coronavirus, the levels being comparable in all animals. Vaccinate not fewer than 10 pregnant cows according to the recommended schedule. Keep not fewer than 5 pregnant cows as unvaccinated controls. Starting at calving, take the colostrum and then milk from each cow and keep it in suitable conditions. Determine individually the protective activity of the colostrum and milk from each cow using calves born from healthy cows, and which may be born by Caesarean section, and maintained in an environment where they are not exposed to infection by bovine coronavirus. Feed colostrum and then milk to each calf every 6 h or according to the recommended schedule. At 5-7 days after birth, challenge each calf by the oral administration of a suitable quantity of a virulent strain of bovine coronavirus. Observe the calves for 7 days. Note the incidence, severity and duration of diarrhoea and the duration and quantity of virus excretion. The vaccine complies with the test if there

is a significant reduction in diarrhoea and virus excretion in calves given colostrum and milk from vaccinated cows compared to those given colostrum and milk from controls.

LABELLING

The label states the recommended schedule for administering colostrum and milk, *post-partum*.

01/2005:1954

CALF ROTAVIRUS DIARRHOEA VACCINE (INACTIVATED)

Vaccinum inactivatum diarrhoeae vituli rotaviro illatae

DEFINITION

Calf rotavirus diarrhoea vaccine (inactivated) is a preparation of one or more suitable strains of bovine rotavirus, inactivated in such a manner that immunogenic properties are maintained. The vaccine is administered to the dam to aid in the control of rotavirus diarrhoea in offspring during the first few weeks of life.

PRODUCTION

Each virus strain is grown separately in suitable cell cultures (5.2.4). The viral suspensions of each strain are harvested separately and inactivated by a method that maintains immunogenicity. The viral suspensions may be purified and concentrated.

The test for inactivation is carried out using 2 passages in cell cultures of the same type as those used for production or in cells shown to be at least as sensitive. The quantity of virus used in the test is equivalent to not less than 100 doses of vaccine. No live virus is detected.

The vaccine may contain an adjuvant.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) in the pregnant cow. The following tests may be used during demonstration of safety and immunogenicity.

Safety. Carry out the test for each proposed route of administration. Administer by a proposed route and at the proposed stage or stages of pregnancy, a double dose of vaccine to each of not fewer than 10 pregnant cows that have not been vaccinated against bovine rotavirus. After the proposed interval, inject 1 dose into each cow. After each injection, measure the body temperature on the day of the injection and on the 4 following days. Observe the cows until calving. No abnormal local or systemic reaction occurs; any effects on gestation and the offspring are noted.

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity of the strain.

BATCH TESTING

Batch potency test. The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a suitable correlation with the test described under Potency has been established.

To obtain a valid assay, it may be necessary to carry out a test using several groups of animals, each receiving

a different dose. For each dose required, carry out the test as follows. Vaccinate not fewer than 5 animals of a suitable species, free from specific antibodies against bovine rotavirus, using 1 injection of a suitable dose. Maintain not fewer than 2 animals as unvaccinated controls. Where the recommended schedule requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval not less than 14 days after the last injection, collect blood from each animal and prepare serum samples. Use a suitable validated test to measure the antibody response. The antibody level is not significantly less than that obtained with a batch that has given satisfactory results in the test described under Potency and there is no significant increase in antibody titre in the controls.

IDENTIFICATION

Injected into animals free from specific antibodies against bovine rotavirus, the vaccine stimulates the formation of such antibodies.

TESTS

Safety. Use cattle not less than 6 months old and preferably having no antibodies against bovine rotavirus or, where justified, use cattle with a low level of such antibodies as long as they have not been vaccinated against bovine rotavirus and administration of the vaccine does not cause an anamnestic response. Administer to each of 2 animals a double dose of vaccine by a recommended route. After 14 days, administer 1 dose to each animal. Observe the animals for 14 days. No abnormal local or systemic reaction occurs.

Inactivation. Carry out a test for residual infectious virus using 10 doses of vaccine and 2 passages in cell cultures of the same type as those used for production of the vaccine or other cell cultures of suitable sensitivity. No live virus is detected. If the vaccine contains an adjuvant which interferes with the test, separate it if possible from the liquid phase of the vaccine by a method that does not inactivate virus nor interfere in any other way with detection of live viruses.

Extraneous viruses. Carry out tests for antibodies on the cattle used for the safety test. Take a blood sample at the end of the second observation period. The vaccine does not stimulate the formation of antibodies against bovine herpes virus 1 (BHV 1), bovine leukaemia virus (BLV) and bovine viral diarrhoea virus (BVDV).

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Use not fewer than 15 pregnant cows, where possible having no antibodies against bovine rotavirus. Where such cows are not available, use cows that: have not been vaccinated against bovine rotavirus; come from a farm where there is no recent history of infection with bovine rotavirus; and have a low level of antibodies against bovine rotavirus, the levels being comparable in all animals. Vaccinate not fewer than 10 pregnant cows according to the recommended schedule. Keep not fewer than 5 pregnant cows as unvaccinated controls. Starting at calving, take the colostrum and then milk from each cow and keep it in suitable conditions. Determine individually the protective activity of the colostrum and milk from each cow using calves born from healthy cows, and which may be born by Caesarean section, and maintained in an environment where they are not exposed to infection by bovine rotavirus. Feed colostrum

and then milk to each calf every 6 h or according to the recommended schedule. At 5-7 days after birth, challenge each calf by the oral administration of a suitable quantity of a virulent strain of bovine rotavirus. Observe the calves for 7 days. Note the incidence, severity and duration of diarrhoea and the duration and quantity of virus excretion. The vaccine complies with the test if there is a significant reduction in diarrhoea and virus excretion in calves given colostrum and milk from vaccinated cows compared to those given colostrum and milk from controls.

LABELLING

The label states the recommended schedule for administering colostrum and milk, *post-partum*.

01/2005:1298

CANINE ADENOVIRUS VACCINE (INACTIVATED)

Vaccinum adenoviro-sis caninae inactivatum

DEFINITION

Canine adenovirus vaccine (inactivated) is a suspension of one or more suitable strains of canine adenovirus 1 (canine contagious hepatitis virus) and/or canine adenovirus 2, inactivated in such a way that adequate immunogenicity is maintained.

PRODUCTION

The test for inactivation is carried out using a quantity of virus equivalent to at least 10 doses of vaccine with 2 passages in cell cultures of the same type as those used for production or in cell cultures shown to be at least as sensitive. No live virus is detected.

The vaccine may contain an adjuvant.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7). The following tests may be used during demonstration of safety and immunogenicity.

Safety. Carry out the test for each recommended route of administration in animals of the minimum age recommended for vaccination. Use a batch of vaccine of the maximum potency likely to be attained.

Use for each test not fewer than 10 dogs that do not have antibodies against canine adenovirus 1 or 2. Administer to each dog a double dose of vaccine. If the recommended schedule requires a second dose, administer one dose after the recommended interval. Observe the dogs for 14 days after the last administration. No abnormal local or systemic reaction occurs.

If the vaccine is intended for use in pregnant bitches, vaccinate bitches at the stage of pregnancy or at different stages of pregnancy according to the recommended schedule. Prolong observation until 1 day after parturition. No abnormal local or systemic reaction occurs. No adverse effects on the pregnancy and offspring are noted.

Immunogenicity. For vaccines intended to protect against hepatitis, the test described under Potency is suitable for demonstration of immunogenicity. If the vaccine is indicated for protection against respiratory signs, a further test to demonstrate immunogenicity for this indication is also necessary.

BATCH TESTING

Batch potency test. The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out for a given vaccine on one or more occasions as

decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable validated alternative test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

IDENTIFICATION

When injected into susceptible animals, the vaccine stimulates the formation of specific antibodies against the type or types of canine adenovirus stated on the label.

TESTS

Safety. Use dogs of the minimum age recommended for vaccination and preferably having no canine adenovirus-neutralising antibodies or, where justified, use dogs with a low level of such antibodies as long as they have not been vaccinated against canine adenovirus and administration of the vaccine does not cause an anamnestic response. Administer a double dose of vaccine by a recommended route to each of 2 dogs. Observe the dogs for 14 days. No abnormal local or systemic reaction occurs.

Inactivation. Carry out a test for residual infectious canine adenovirus using 10 doses of vaccine by inoculation into sensitive cell cultures; make a passage after 6-8 days and maintain the cultures for 14 days. No live virus is detected. If the vaccine contains an adjuvant, separate the adjuvant from the liquid phase by a method that does not inactivate or otherwise interfere with the detection of live virus.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Use 7 dogs of the minimum age recommended for vaccination and that do not have antibodies against canine adenovirus. Vaccinate 5 of the animals by a recommended route and according to the recommended schedule. Keep the other 2 dogs as controls. 21 days later inject intravenously into each of the 7 animals a quantity of a virulent strain of canine adenovirus sufficient to cause death or typical signs of the disease in a susceptible dog. Observe the animals for a further 21 days. Dogs displaying typical signs of serious infection with canine adenovirus are killed humanely to avoid unnecessary suffering. The test is invalid and must be repeated if one or both of the controls do not die from or display typical signs of serious infection with canine adenovirus. The vaccine complies with the test if the vaccinated animals remain in good health.

LABELLING

The label states the type or types of canine adenovirus present in the vaccine.

01/2005:1951

CANINE ADENOVIRUS VACCINE (LIVE)

Vaccinum adenoviro-sidis caninae vivum

DEFINITION

Canine adenovirus vaccine (live) is a preparation of 1 or more suitable strains of canine adenovirus 2. This monograph applies to vaccines intended for active immunisation of dogs against canine contagious hepatitis and/or respiratory disease caused by canine adenovirus.

PRODUCTION

The virus strain is propagated in suitable cell cultures (5.2.4). The viral suspension is harvested, titrated and may be mixed with a suitable stabilising solution. The vaccine may be freeze-dried.

CHOICE OF VACCINE STRAIN

The vaccine is shown to be satisfactory with respect to safety (5.2.6), absence of increase in virulence and immunogenicity (5.2.7). The following tests may be used during demonstration of safety, absence of increase in virulence and immunogenicity.

Safety. The test is carried out for each route of administration to be stated on the label. Use not fewer than 5 puppies of the minimum age recommended for vaccination and that do not have antibodies to canine adenovirus. Administer to each puppy by a recommended route a quantity of virus corresponding to not less than 10 times the maximum titre that may be expected in a dose of vaccine. Observe the dogs for 14 days. The puppies remain in good health and no abnormal local or systemic reaction occurs.

If the vaccine is intended for use or may be used in pregnant bitches, administer the virus to 5 bitches at the recommended stage or at a range of stages of pregnancy according to the recommended schedule. Prolong the observation period until 1 day after parturition. The bitches remain in good health and there is no abnormal local or systemic reaction. No adverse effects on the pregnancy or the offspring are noted.

Increase in virulence. Administer by a recommended route to each of 2 puppies, 5-7 weeks old and which do not have antibodies against canine adenovirus, a quantity of virus that will allow recovery of virus for the passages described below. Kill the puppies 4-6 days later. Remove from each puppy nasal and pharyngeal mucosa, tonsils, lung, spleen and, if they are likely to contain virus, liver and kidney. Pool the samples; administer by a suitable route, for example intranasally, 1 ml of the pooled organ suspension to each of 2 other puppies of the same age and susceptibility; carry out these operations at least 5 times; verify the presence of the virus at each passage by direct or indirect means. If the virus has disappeared, carry out a second series of passages. Inoculate virus from the highest recovered passage level to 5 puppies of the minimum age recommended for vaccination, observe for 14 days and compare the reactions that occur with those seen in the test for safety described above. There is no indication of an increase of virulence as compared with the non-passaged virus.

Immunogenicity. For vaccines intended to protect against hepatitis, test A described under Potency is suitable for demonstration of Immunogenicity. For vaccines intended to protect against respiratory signs, test B described under Potency is suitable for demonstration of immunogenicity.

BATCH TESTING

If the test for Potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot.

IDENTIFICATION

The vaccine mixed with monospecific antiserum against canine adenovirus 2 no longer infects susceptible cell cultures.

TESTS

Safety. Use 2 puppies not older than the minimum age recommended for vaccination and which do not have antibodies against canine adenovirus. Administer 10 doses of the vaccine to each dog by a recommended route. Observe for 14 days. The dogs remain in good health and no abnormal local or systemic reaction occurs.

Extraneous viruses. Mix the vaccine with a suitable monospecific antiserum against canine adenovirus 2 and inoculate into cell cultures known for their susceptibility to viruses pathogenic for the dog. Carry out a passage after 6-8 days and maintain the cultures for a total of 14 days. No cytopathic effect develops and the cells show no evidence of the presence of haemadsorbing agents.

Bacterial and fungal contamination. The vaccine, reconstituted if necessary, complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

Mycoplasmas (2.6.7). The vaccine, reconstituted if necessary, complies with the test for mycoplasmas.

Virus titre. Reconstitute the vaccine, if necessary, and titrate in suitable cell cultures. 1 dose of the vaccine contains not less than the quantity of virus equivalent to the minimum virus titre stated on the label.

POTENCY

Depending on the indications for the vaccine, it complies with test A and/or B for potency.

- A. Use 7 puppies of the minimum age recommended for vaccination and that do not have antibodies against canine adenovirus. Vaccinate 5 of the animals by a recommended route and according to the recommended schedule. Keep the other 2 dogs as controls. 21 days later, inject intravenously into each of the 7 animals a quantity of a virulent strain of canine adenovirus 1 (canine contagious hepatitis virus) sufficient to cause death or typical signs of the disease in a susceptible dog. Observe the animals for a further 21 days. Dogs displaying typical signs of serious infection with canine adenovirus are killed humanely to avoid unnecessary suffering. The test is invalid and must be repeated if 1 or both of the controls do not die from or display typical signs of serious infection with canine adenovirus. The vaccine complies with the test if the vaccinated animals remain in good health showing no clinical signs except for a possible transient elevated rectal temperature.
- B. Use 20 dogs of the minimum age recommended for vaccination and that do not have antibodies against canine adenovirus. Vaccinate 10 of the dogs by a recommended route and according to the recommended schedule. Keep the other 10 dogs as controls. 21 days later, administer intranasally to each of the 20 animals a quantity of a virulent strain of canine adenovirus 2 sufficient to cause typical signs of respiratory disease in a susceptible dog. Observe the animals daily for a further 10 days. Record the incidence of signs of respiratory and general disease in each dog (for example, sneezing, coughing, nasal and lachrymal discharge, loss of appetite). Collect nasal swabs or washings from each dog daily from days 2 to 10 after challenge and test these samples to determine the presence and titre of excreted virus. The vaccine complies with the test if there is a notable decrease in the incidence and severity of clinical signs and in virus excretion in vaccinates compared to controls.

01/2005:0448 IDENTIFICATION

**CANINE DISTEMPER VACCINE (LIVE),
FREEZE-DRIED****Vaccinum morbi Carrei vivum
cryodesiccatum ad canem****DEFINITION**

Freeze-dried canine distemper vaccine (live) is a preparation of a strain of distemper virus that is attenuated for dogs.

PRODUCTION

The virus is propagated in suitable cell cultures (5.2.4) or in fertilised hen eggs from flocks free from specified pathogens (5.2.2). The viral suspension is harvested, titrated and may be mixed with a suitable stabilising solution. The vaccine is then freeze-dried.

CHOICE OF VACCINE STRAIN

The vaccine strain is shown to be satisfactory with respect to safety (5.2.6), absence of increase in virulence and immunogenicity (5.2.7). The following tests may be used during demonstration of safety, absence of increase in virulence and immunogenicity.

Safety. The test is carried out for each recommended route of administration. Use five susceptible puppies of the minimum age recommended for vaccination and that do not have antibodies against canine distemper virus. Administer to each puppy by a recommended route a quantity of virus corresponding to not less than ten times the maximum titre that may be expected in a dose of vaccine. Observe the puppies for 42 days. The puppies remain in good health and there is no abnormal local or systemic reaction.

If the vaccine is intended for use in pregnant bitches, administer the virus to five bitches at the recommended stage of pregnancy or at a range of stages of pregnancy according to the recommended schedule. Prolong observation until 1 day after parturition. The dogs remain in good health and there is no abnormal local or systemic reaction. No adverse effects on the pregnancy or the offspring are noted.

Increase in virulence. Administer by a recommended route to each of two puppies, 5 to 7 weeks old and which do not have antibodies against canine distemper virus a quantity of virus corresponding to one dose of vaccine. Kill the puppies 5 to 10 days later, remove nasal mucosa, tonsils, thymus, spleen and the lungs and their local lymph nodes from each puppy and pool the samples; administer intranasally 1 ml of the pooled organ suspension to each of two other puppies of the same age and susceptibility; carry out these operations at least five times; verify the presence of the virus at each passage by direct or indirect means. If the virus has disappeared, carry out a second series of passages. Inoculate virus from the highest recovered passage level to puppies, observe for 42 days and compare any reactions that occur with those seen in the test for safety described above. There is no indication of an increase of virulence as compared with the non-passaged virus.

Immunogenicity. The test described under Potency may be used to demonstrate the immunogenicity of the strain.

BATCH TESTING

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot.

IDENTIFICATION

The vaccine reconstituted as stated on the label and mixed with a monospecific distemper antiserum against canine distemper virus no longer provokes cytopathic effects in susceptible cell cultures.

TESTS

Safety. Use two puppies of the minimum age recommended for vaccination and which do not have antibodies against canine distemper virus. Administer ten doses of the vaccine to each dog by a recommended route. Observe for 14 days. The dogs remain in good health and no abnormal local or systemic reaction occurs.

Extraneous viruses. Mix the vaccine with a suitable monospecific antiserum against canine distemper virus and inoculate into cell cultures known for their susceptibility to viruses pathogenic for the dog. Carry out a passage after 6 to 8 days and maintain the cultures for 14 days. No cytopathic effect develops and the cells show no evidence of the presence of haemadsorbing agents.

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility prescribed under *Vaccines for veterinary use (0062)*.

Mycoplasmas (2.6.7). The reconstituted vaccine complies with the test for mycoplasmas.

Virus titre. Titrate the reconstituted vaccine in suitable cell cultures. One dose of the vaccine contains not less than the quantity of virus equivalent to the minimum virus titre stated on the label.

POTENCY

Use seven susceptible puppies, 8 to 16 weeks old and free from antibodies against canine distemper virus. Vaccinate five puppies according to the instructions for use. Keep the two other animals as controls. Observe all the animals for 21 days. Inject intravenously into each animal a quantity of canine distemper virus sufficient to cause in a susceptible dog death or typical signs of the disease. Observe the animals for a further 21 days. Dogs displaying typical signs of serious infection with canine distemper virus are killed humanely to avoid unnecessary suffering. The test is not valid and must be repeated if one or more of the control animals do not either die of distemper or display typical signs of serious infection. The vaccine complies with the test if the vaccinated animals remain in good health.

01/2005:0447

**CANINE LEPTOSPIROSIS VACCINE
(INACTIVATED)****Vaccinum leptospirosis caninae inactivatum****DEFINITION**

Canine leptospirosis vaccine (inactivated) is a suspension of inactivated whole organisms and/or antigenic extract(s) of one or more suitable strains of one or more of *Leptospira interrogans* serovar canicola, serovar icterohaemorrhagiae or any other epidemiologically appropriate serovar, inactivated and prepared in such a way that adequate immunogenicity is maintained. This monograph applies to vaccines intended for active immunisation of dogs against leptospirosis.

PRODUCTION

The seed material is cultured in a suitable medium; each strain is cultivated separately. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity are verified on the harvest using suitable methods. After cultivation, the bacterial harvests are collected separately and inactivated by a suitable method. The antigen may be concentrated. The vaccine may contain an adjuvant.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) in dogs. As part of the studies to demonstrate the suitability of the vaccine with respect to these characteristics the following tests may be carried out.

Safety. The test is carried out for each route of administration to be stated on the label and in animals of each category for which the vaccine is intended. For each test, use not fewer than 10 dogs that do not have antibodies against the principal *L. interrogans* serovars (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis). Use a batch of vaccine containing not less than the maximum antigen content and/or potency that may be expected in a batch of vaccine. Administer to each animal a double dose of vaccine. If the recommended schedule requires a second dose, administer 1 dose after the recommended interval. Observe the animals for at least 14 days after the last administration. Record body temperatures the day before each vaccination, at vaccination, 4 h later and daily for 4 days. If the vaccine is intended for use or may be used in pregnant bitches, vaccinate the animals at the recommended stage of pregnancy or at a range of stages of pregnancy and prolong the observation period until 1 day after whelping. The vaccine complies with the test if no animal shows an abnormal local or systemic reaction or clinical signs of disease or dies from a cause attributable to the vaccine. In addition, if the vaccine is for use in pregnant animals, no adverse effects on the pregnancy and offspring are noted.

Immunogenicity. As part of the studies to demonstrate the suitability of the vaccine with respect to immunogenicity and compliance with the claims to be stated on the label, the test described under Potency may be carried out for each proposed route of administration and using vaccine of minimum antigen content and/or potency.

BATCH POTENCY TEST

The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority. Where the test is not carried out, one of the following tests may be used.

A. For vaccines with or without adjuvants

If leptospira from more than 1 serovar (for example *L. interrogans* serovar canicola and serovar icterohaemorrhagiae) has been used to prepare the vaccine, carry out a batch potency test for each serovar against which protective immunity is claimed on the label. Inject 1/40 of the dose for dogs stated on the label subcutaneously into each of 5 healthy hamsters not more than 3 months old, which do not have antibodies to the principal serovars of *L. interrogans* (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis) and which have been obtained from a regularly tested and certified leptospira-free source. After 15-20 days, inoculate intraperitoneally into each of the vaccinated animals and into an equal number of non-vaccinated controls

derived from the same certified leptospira-free source, a suitable quantity of a virulent culture of leptospirae of the serovar against which protective immunity is claimed on the label. The vaccine complies with the test if not fewer than 4 of the 5 control animals die showing typical signs of leptospira infection within 14 days of receiving the challenge suspension and if not fewer than 4 of the 5 vaccinated animals remain in good health for 14 days after the death of 4 control animals.

B. For vaccines with or without adjuvants

A suitable validated sero-response test may be carried out. Vaccinate each animal in a group of experimental animals with a suitable dose. Collect blood samples after a suitable, fixed time after vaccination. For each of the serovars present in the vaccine, an *in vitro* test is carried out on individual blood samples to determine the antibody response to one or more antigenic components which are indicators of protection and which are specific for that serovar. The criteria for acceptance are set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

C. For vaccines without adjuvants

For each of the serovars present in the vaccine, a suitable validated *in vitro* test may be carried out to determine the content of one or more antigenic components which are indicators of protection and which are specific for that serovar. The criteria for acceptance are set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

IDENTIFICATION

When injected into healthy seronegative animals, the vaccine stimulates the production of specific antibodies to the leptospira serovar(s) present in the vaccine. If test C is used for batch potency test, it also serves to identify the vaccine.

TESTS

Safety. Use 2 dogs of the minimum age recommended for vaccination and which do not have antibodies to the leptospira serovar(s) present in the vaccine. Administer 2 doses of the vaccine to each dog by a recommended route. Observe the animals for 14 days. The animals remain in good health and no abnormal local or systemic reaction occurs.

Inactivation. Carry out a test for live leptospirae by inoculation of a specific medium. Inoculate 1 ml of the vaccine into 100 ml of the medium. Incubate at 30 °C for 14 days, subculture into a further quantity of the medium and incubate both media at 30 °C for 14 days: no growth occurs in either medium. At the same time, carry out a control test by inoculating a further quantity of the medium with the vaccine together with a quantity of a culture containing approximately 100 leptospirae and incubating at 30 °C: growth of leptospirae occurs within 14 days.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062).

POTENCY

For each type of the serovars against which protective immunity is claimed on the label, carry out a separate test with a challenge strain representative of that serovar.

Use not fewer than 12 dogs of the minimum age recommended for vaccination and free from specific antibodies against the principal serovars of *L. interrogans* (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis). Vaccinate half of the animals by a recommended route and according to the recommended schedule. Keep the

remaining animals as controls. 25-28 days after the last vaccination, infect all the animals by the conjunctival and/or intraperitoneal route with a suitable quantity of a virulent strain of the relevant *L. interrogans* serovar. Observe the animals for a further 28 days. Examine the dogs daily and record and score clinical signs observed post-challenge and any deaths that occur. If an animal shows marked signs of disease, it is killed. Monitor body temperatures each day for the first week after challenge. Collect blood samples from each animal on days 0, 2, 3, 4, 5, 8 and 11 post challenge. Collect urine samples from each animal on days 0, 3, 5, 8, 11, 14, 21 and 28 post challenge. Kill surviving animals at the end of the observation period. Carry out post-mortem examination on any animal that dies during the observation period and on the remainder when killed at the end of the observation period. In particular, examine the liver and kidneys for macroscopic and microscopic signs of leptospira infection. A sample of each kidney is collected and each blood, urine and kidney sample is tested for the presence of challenge organisms by re-isolation or by another suitable method. The blood samples are also analysed to detect biochemical and haematological changes indicative of infection and these are also scored.

The test is invalid if: samples give positive results on day 0; *L. interrogans* serovar challenge strain is re-isolated from or demonstrated by another suitable method to be present in fewer than 2 samples on fewer than 2 different days, to show infection has been established in fewer than 80 per cent of the control animals.

The vaccine complies with the test if: at least 80 per cent of the vaccinates show no more than mild signs of disease (for example, transient hyperthermia) and, depending on the *L. interrogans* serovar used for the challenge, one or more of the following is also shown:

- where the vaccine is intended to have a beneficial effect against clinical signs, the clinical scores and haematological and biochemical scores are statistically lower for the vaccinates than for the controls,
- where the vaccine is intended to have a beneficial effect against infection, the number of days that the organisms are detected in the blood is statistically lower for the vaccinates than for the controls,
- where the vaccine is intended to have a beneficial effect against urinary tract infection and excretion, the number of days that the organisms are detected in the urine and the number of kidney samples in which the organisms are detected is statistically lower for the vaccinates than for the controls.

LABELLING

The label states:

- the serovar(s) used to prepare the vaccine,
- the serovar(s) against which the protection is claimed.

01/2005:1955

CANINE PARAINFLUENZA VIRUS VACCINE (LIVE)

Vaccinum parainfluenzae viri canini vivum

DEFINITION

Canine parainfluenza virus vaccine (live) is a preparation of a suitable attenuated strain of canine parainfluenza virus for dogs. The vaccine is intended for the protection of dogs against respiratory signs of infection with parainfluenza virus of canine origin.

PRODUCTION

The virus is propagated in suitable cell cultures (5.2.4). The viral suspension is harvested, titrated and may be mixed with a suitable stabilising solution. The vaccine may be freeze-dried.

CHOICE OF VACCINE STRAIN

The vaccine is shown to be satisfactory with respect to safety, absence of increase in virulence and immunogenicity. The following tests may be used during demonstration of safety (5.2.6), absence of increase in virulence and immunogenicity (5.2.7).

Safety. The test is carried out for each route of administration stated on the label. Use not fewer than 5 susceptible puppies of the recommended minimum age for vaccination and that do not have antibodies against parainfluenza virus of canine origin. Administer to each puppy by a recommended route a quantity of virus corresponding to not less than 10 times the maximum titre that may be expected in a dose of vaccine. Observe the puppies for 21 days. The puppies remain in good health and there is no abnormal local or systemic reaction.

If the vaccine is intended for use in pregnant bitches, administer the virus to not fewer than 5 bitches at the recommended stage or stages of pregnancy and according to the recommended schedule. Prolong the observation period until 1 day after whelping. The dogs remain in good health and there is no abnormal local or systemic reaction. No adverse effects on the pregnancy or the offspring are noted.

Increase in virulence. Administer intranasally and by a recommended route to each of 2 puppies, 5 to 7 weeks old and which do not have antibodies against parainfluenza virus of canine origin, a quantity of virus that will allow recovery of virus for the passages described below. Use vaccine virus at the least attenuated passage level that will be present in a batch of the vaccine. Collect nasal swabs from each dog daily from 3 to 10 days after inoculation. Inoculate the suspension from the swabs into suitable cell cultures to verify the presence of virus. Use the suspension from the swabs that contain the maximum amount of virus and administer intranasally 1 ml of the suspension into each of 2 other puppies of the same age and susceptibility. This operation is then repeated at least 5 times. If the virus is not recovered at a given passage level, a second series of passages is carried out. Inoculate virus from the highest recovered passage level to not fewer than 5 puppies, observe for 21 days and compare any reactions that occur with those seen in the test for safety described above. There is no indication of an increase in virulence as compared with the non-passaged virus.

Immunogenicity. The test described under Potency is suitable to demonstrate the immunogenicity of the strain.

BATCH TESTING

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot.

IDENTIFICATION

Carry out an immunofluorescence test in suitable cell cultures, using a monospecific antiserum.

TESTS

Safety. Use 2 puppies not older than the minimum age recommended for vaccination and which do not have antibodies against parainfluenza virus of canine origin. Administer a volume containing 10 doses of the vaccine into

each puppy by a recommended route. Observe for 14 days. The puppies remain in good health and no abnormal local or systemic reaction occurs.

Extraneous viruses. Neutralise the vaccine virus using a monospecific antiserum and inoculate into cell cultures known for their susceptibility to viruses pathogenic for the dog. Carry out a passage after 6 to 8 days and maintain the cultures for a total of 14 days. No cytopathic effect develops and the cells show no evidence of the presence of haemadsorbing agents.

Bacterial and fungal contamination. The vaccine, reconstituted if necessary, complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

Mycoplasmas (2.6.7). The vaccine, reconstituted if necessary, complies with the test for mycoplasmas.

Virus titre. Reconstitute the vaccine, if necessary, and titrate in suitable cell cultures. 1 dose of the vaccine contains not less than the quantity of virus equivalent to the minimum virus titre stated on the label.

POTENCY

Use not fewer than 15 susceptible puppies of the minimum age recommended for vaccination and which do not have antibodies against parainfluenza virus of canine origin. Vaccinate not fewer than 10 of the puppies according to the instructions for use. Keep not fewer than 5 other puppies as controls. Observe all the animals for not less than 21 days after the last vaccination. Administer by the intratracheal or intranasal route to each animal a quantity of a virulent strain of parainfluenza virus of canine origin sufficient to establish infection with the virus in a susceptible dog. Observe the animals for a further 14 days. Collect nasal swabs or washings from each dog daily from day 2 to 10 after challenge and test these samples for the presence of excreted virus. Use a scoring system to record the incidence of coughing in each dog. The test is not valid if more than 1 of the control animals shows neither coughing nor the excretion of the challenge virus. The vaccine complies with the test if the scores for coughing or virus excretion for the vaccinated animals are significantly lower than in the controls.

01/2005:0795

CANINE PARVOVIRUS VACCINE (INACTIVATED)

Vaccinum parvovirus caninae inactivatum

DEFINITION

Inactivated canine parvovirus vaccine is a liquid or freeze-dried preparation of canine parvovirus inactivated by a suitable method.

PRODUCTION

The virus is propagated in suitable cell cultures (5.2.4). The virus may be purified and concentrated.

A test for residual live virus is carried out on the bulk harvest of each batch to confirm inactivation of the canine parvovirus. The quantity of inactivated virus used in the test is equivalent to not less than 100 doses of the vaccine. The vaccine is inoculated into suitable non-confluent cells; after incubation for 8 days, a subculture is made using trypsinised cells. After incubation for a further 8 days, the

cultures are examined for residual live parvovirus by an immunofluorescence test. The immunofluorescence test may be supplemented by a haemagglutination test or other suitable tests on the supernatant of the cell cultures. No live virus is detected.

The vaccine may contain an adjuvant or adjuvants.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety and immunogenicity in dogs. The following test may be used in the demonstration of efficacy (5.2.7).

Immunogenicity. 7 susceptible dogs of the minimum age recommended for vaccination are used. A blood sample is drawn from each dog and tested individually for antibodies against canine parvovirus to determine susceptibility. 5 dogs are vaccinated according to the recommended schedule. 2 dogs are kept as controls. 20 to 22 days after the last vaccination each of the dogs receives by the oronasal route a suspension of pathogenic canine parvovirus. The dogs are observed for 14 days. Haemagglutination tests are carried out to detect virus in the faeces. The test is not valid unless the 2 control dogs show typical signs of the disease or leucopenia and excretion of the virus. The vaccine complies with the test if the 5 vaccinated dogs remain in excellent health and show no sign of the disease nor leucopenia and if the maximum titre of virus excreted in the faeces is less than 1/100 of the geometric mean of the maximum titres found in the controls.

IDENTIFICATION

When injected into dogs, the vaccine stimulates the production of antibodies against canine parvovirus.

TESTS

Safety. Use dogs of the minimum age recommended for vaccination and preferably having no canine parvovirus antibodies or, where justified, use dogs with a low level of such antibodies as long as they have not been vaccinated against canine parvovirus and administration of the vaccine does not cause an anamnestic response. Administer a double dose of vaccine by a recommended route to each of 2 dogs. Observe the animals for 14 days. No abnormal local or systemic reaction occurs.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Carry out test A or test B.

A. Inject subcutaneously into each of 5 guinea-pigs, free from specific antibodies, half of the dose stated on the label. After 14 days, inject again half of the dose stated on the label. 14 days later, collect blood samples and separate the serum. Inactivate each serum by heating at 56 °C for 30 min. To 1 volume of each serum add 9 volumes of a 200 g/l suspension of *light kaolin R* in *phosphate buffered saline pH 7.4 R*. Shake each mixture for 20 min. Centrifuge, collect the supernatant liquid and mix with 1 volume of a concentrated suspension of pig erythrocytes. Allow to stand at 4 °C for 60 min and centrifuge. The dilution of the serum obtained is 1:10. Using each serum, prepare a series of twofold dilutions. To 0.025 ml of each of the latter dilutions add 0.025 ml of a suspension of canine parvovirus antigen containing 4 haemagglutinating units. Allow to stand at 37 °C for 30 min and add 0.05 ml of a suspension of pig erythrocytes containing 30×10^6 cells per millilitre. Allow to stand at 4 °C for 90 min and note the last dilution of serum that still completely inhibits haemagglutination.

The vaccine complies with the test if the median antibody titre of the sera collected after the second vaccination is not less than 1/80.

- B. Vaccinate, according to the schedule stated on the label, 2 healthy susceptible dogs, 8 to 12 weeks old and having antibody titres less than 4 ND₅₀ (50 per cent neutralising dose) per 0.1 ml of serum measured by the method described below. 14 days after vaccination, examine the serum of each animal as follows. Heat the serum at 56 °C for 30 min and prepare serial dilutions using a medium suitable for canine cells. Add to each dilution an equal volume of a virus suspension containing an amount of virus such that when the volume of serum-virus mixture appropriate for the assay system is inoculated into cell cultures, each culture receives approximately 10⁴ CCID₅₀. Incubate the mixtures at 37 °C for 1 h and inoculate 4 canine cell cultures with a suitable volume of each mixture. Incubate the cell cultures at 37 °C for 7 days, passage and incubate for a further 7 days. Examine the cultures for evidence of specific cytopathic effects and calculate the antibody titre. The vaccine complies with the test if the mean titre is not less than 32 ND₅₀ per 0.1 ml of serum. If one dog fails to respond, repeat the test using 2 more dogs and calculate the result as the mean of the titres obtained from all of the 3 dogs that have responded.

01/2005:0964

CANINE PARVOVIRUS VACCINE (LIVE)

Vaccinum parvovirus caninae vivum

DEFINITION

Canine parvovirus vaccine (live) is a preparation of a strain of canine parvovirus that is attenuated for the dog.

PRODUCTION

The attenuated virus is grown in suitable cell cultures (5.2.4).

The viral suspension is harvested, titrated and mixed with a suitable stabilising solution. The vaccine may be freeze-dried.

CHOICE OF VACCINE STRAIN

Only a virus strain shown to be satisfactory with respect to safety, irreversibility of attenuation, and immunogenicity may be used in the preparation of the vaccine. The following tests are used in the demonstration of safety (5.2.6) and efficacy (5.2.7).

Safety. Each test is carried out for each recommended route of administration.

5 susceptible puppies of the minimum age recommended for vaccination and having no haemagglutination-inhibiting antibodies against canine parvovirus are used for the test. A count of white blood cells in circulating blood is made on days 4, 2 and 0 before injection of the vaccine strain. Each puppy receives by a recommended route a quantity of virus corresponding to not less than 10 times the maximum virus titre that may be expected in a batch of vaccine and at the lowest passage level. The puppies are observed for 21 days. A count of white blood cells in circulating blood is made on days 3, 5, 7 and 10 after the injection. The puppies remain in good health and there is no abnormal local or systemic reaction. Any diminution in the number of circulating white blood cells is not greater than 50 per cent of the initial number determined as the average of the 3 values found before injection of the vaccine strain.

A quantity of virus corresponding to not less than 10 times the maximum titre that may be expected in a batch of vaccine and at the lowest passage level is administered by one of the recommended routes to each of 5 susceptible puppies. Five puppies are kept as controls. 2 puppies from each group are killed at 14 days and the 3 remaining puppies from each group at 21 days and histological examination of the thymus of each animal is carried out. Slight hypoplasia of the thymus may be evident after 14 days. The strain is not acceptable if damage is evident after 21 days.

Irreversibility of attenuation. Use 2 susceptible puppies of the minimum age recommended for vaccination and which do not have haemagglutination-inhibiting antibodies against canine parvovirus. Administer to each puppy, by a recommended route, a quantity of virus corresponding to 10 times the maximum titre that may be expected in a batch of vaccine. From the second to the tenth day after administration of the virus, the faeces are collected from each puppy and checked for the presence of the virus; faeces containing virus are pooled. 1 ml of the suspension of pooled faeces is administered by the oronasal route to each of 2 other puppies of the same age and susceptibility; this operation is carried out 4 times. The presence of virus is verified at each passage. If the virus is not found, a second identification of passages is carried out; if the virus is not found in one of the second identification of passages, the vaccine strain complies with the test. No puppy dies or shows signs attributable to the vaccine. No indication of increase of virulence compared to the original vaccinal virus is observed; account is taken, notably, of the count of white blood cells, of results of histological examination of the thymus and of the titre of excreted virus.

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity of the strain.

BATCH TESTING

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot, subject to agreement by the competent authority.

IDENTIFICATION

The vaccine is grown in a susceptible cell line in a substrate suitable for presenting for fluorescent antibody or immunoperoxidase tests. Suitable controls are included. A proportion of the cells is tested with a monoclonal antibody specific for canine parvovirus and a proportion of the cells tested with a monoclonal antibody specific for feline parvovirus. Canine parvovirus antigen is detected but no feline parvovirus is detected in the cells inoculated with the vaccine.

TESTS

Safety. Use 2 dogs of the minimum age recommended for vaccination and having no haemagglutination-inhibiting antibodies against canine parvovirus. Administer 10 doses of the vaccine to each dog by a recommended route. Observe for 14 days. No abnormal local or systemic reaction occurs.

Extraneous viruses. Mix the vaccine with a suitable antiserum against canine parvovirus and inoculate into cell cultures known for their susceptibility to viruses pathogenic for the dog. No cytopathic effect develops. There is no sign of haemagglutinating or haemadsorbing agents and no other sign of the presence of extraneous viruses.

Bacterial and fungal contamination. The vaccine, reconstituted if necessary, complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

Mycoplasmas (2.6.7). The vaccine, reconstituted if necessary, complies with the test for mycoplasmas.

Virus titre. Reconstitute the vaccine, if necessary, as stated on the label and titrate in suitable cell cultures. One dose of the vaccine contains not less than the quantity of virus equivalent to the minimum virus titre stated on the label.

POTENCY

Use 7 susceptible puppies of the minimum age recommended for vaccination and which do not have haemagglutination-inhibiting antibodies against canine parvovirus. Keep 2 of the puppies as controls and to each of the others inject by a recommended route the quantity of virus equivalent to the minimum titre stated on the label. Observe all the puppies for 20 to 22 days and then inoculate to each of them by the oronasal route a suspension of virulent canine parvovirus. Observe all the animals for 14 days. Carry out a haemagglutination test for the virus in the faeces. The test is not valid unless the 2 control puppies show typical signs of the disease and/or leucopenia and excretion of the virus. The vaccine complies with the test if the 5 vaccinated puppies remain in excellent health and show no sign of the disease nor leucopenia and if the maximum titre of virus excreted in the faeces is less than 1/100 of the geometric mean of the maximum titres found in the controls.

01/2005:0360

CLOSTRIDIUM BOTULINUM VACCINE FOR VETERINARY USE

*Vaccinum clostridii botulini
ad usum veterinarium*

DEFINITION

Clostridium botulinum vaccine for veterinary use is prepared from a culture in liquid medium of *Clostridium botulinum* type C or type D or a mixture of these types. The whole culture or its filtrate or a mixture of the two is inactivated in such a manner that toxicity is eliminated and immunogenic activity is retained.

The preparation may be adsorbed, precipitated or concentrated. It may be treated with a suitable adjuvant and may be freeze-dried.

The identification, the tests and the determination of potency apply to the liquid preparation and to the freeze-dried preparation reconstituted as stated on the label.

IDENTIFICATION

When injected into a healthy susceptible animal, the vaccine provokes the formation of specific antibodies against the type or types of *C. botulinum* from which the vaccine was prepared.

TESTS

Safety. Use 2 animals of one of the species for which the vaccine is intended and that have not been vaccinated against *C. botulinum*. Administer to each animal, by a recommended route, twice the maximum dose stated on the label. Observe the animals for 7 days. No abnormal local or systemic reaction occurs.

Residual toxicity. Inject 0.5 ml of the vaccine subcutaneously into each of 5 mice, each weighing 17 g to 22 g. Observe the animals for 7 days. No abnormal local or systemic reaction occurs.

Sterility. It complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Use healthy white mice from a uniform stock, each weighing 18 g to 20 g. Use as challenge dose a quantity of a toxin of *C. botulinum* of the same type as that used in the preparation of the vaccine corresponding to 25 times the paralytic dose 50 per cent, a paralytic dose 50 per cent being the quantity of toxin which, when injected intraperitoneally into mice, causes paralysis in 50 per cent of the animals within an observation period of 7 days. If 2 types of *C. botulinum* have been used in the preparation of the vaccine, carry out the potency determination for each. Dilute the vaccine to be examined 1 in 8 using a 9 g/l solution of *sodium chloride R*. Inject 0.2 ml of the dilution subcutaneously into each of 20 mice. After 21 days, inject the challenge dose intraperitoneally into each of the vaccinated mice and into each of 10 control mice. Observe the mice for 7 days and record the number of animals which show signs of botulism. All the control mice show signs of botulism during the observation period. The vaccine passes the test if not fewer than 80 per cent of the vaccinated mice are protected.

LABELLING

The label states:

- the type or types of *C. botulinum* from which the vaccine has been prepared,
- whether the preparation is a toxoid or a vaccine prepared from a whole inactivated culture or a mixture of the two,
- that the preparation be shaken before use.

01/2005:0361

CLOSTRIDIUM CHAUVOEI VACCINE FOR VETERINARY USE

*Vaccinum clostridii chauvoei
ad usum veterinarium*

DEFINITION

Clostridium chauvoei vaccine for veterinary use is prepared from a culture in liquid medium of one or more suitable strains of *Clostridium chauvoei*. The whole culture is inactivated in such a manner that toxicity is eliminated and immunogenic activity is retained. Inactivated cultures may be treated with a suitable adjuvant.

IDENTIFICATION

The vaccine protects susceptible animals against infection with *C. chauvoei*.

TESTS

Safety. Use 2 animals of one of the species for which the vaccine is intended and that have not been vaccinated against *C. chauvoei*. Administer to each animal at a single site, by a recommended route, twice the maximum dose stated on the label. Observe the animals for 7 days. No abnormal local or systemic reaction occurs.

Sterility. It complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Inject subcutaneously into not fewer than 10 healthy guinea-pigs, each weighing 350 g to 450 g, a quantity of the vaccine not exceeding the minimum dose stated on the label as the first dose. After 28 days, inject into the same animals a quantity of the vaccine not exceeding the minimum dose stated on the label as the second dose. 14 days after the second vaccination, inoculate intramuscularly into each

of the vaccinated guinea-pigs and into each of 5 control animals a suitable quantity of a virulent culture, or of a spore suspension, of *C. chauvoei*, activated if necessary with an activating agent such as calcium chloride. The vaccine complies with the test if not more than 10 per cent of the vaccinated guinea-pigs die from *C. chauvoei* infection within 5 days and all the control animals die from *C. chauvoei* infection within 48 h of challenge or within 72 h if a spore suspension was used for the challenge. If more than 10 per cent but not more than 20 per cent of the vaccinated animals die, repeat the test. The vaccine complies with the test if not more than 10 per cent of the second group of vaccinated animals die within 5 days and all of the second group of control animals die within 48 h of challenge or within 72 h if a spore suspension was used for the challenge. To avoid unnecessary suffering following virulent challenge, moribund animals are killed and are then considered to have died from *C. chauvoei* infection.

LABELLING

The label states that the preparation is to be shaken before use.

CLOSTRIDIUM NOVYI (TYPE B) VACCINE FOR VETERINARY USE

Vaccinum clostridii novyi B
ad usum veterinarium

DEFINITION

Clostridium novyi (type B) vaccine for veterinary use is prepared from a liquid culture of a suitable strain of *Clostridium novyi* (type B).

PRODUCTION

The whole culture or its filtrate or a mixture of the two is inactivated in such a manner that toxicity is eliminated and immunogenic activity is retained. Toxoids and/or inactivated cultures may be treated with a suitable adjuvant, after concentration if necessary.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7). For the latter, it shall be demonstrated that for each target species the vaccine, when administered according to the recommended schedule, stimulates an immune response (for example, induction of antibodies) consistent with the claims made for the product.

BATCH TESTING

Residual toxicity. The test for residual toxicity may be omitted by the manufacturer, since a test for detoxification is carried out immediately after the detoxification process and, when there is risk of reversion, a second test is carried out at as late a stage as possible during the production process.

Batch potency test. The test described under Potency is not necessarily carried out for routine testing of batches of vaccine. It is carried out for a given vaccine on one or more occasions as decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable validated alternative test is carried out, the criteria

for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Vaccinate rabbits as described under Potency and prepare sera. Determine the level of antibodies against the alpha toxin of *C. novyi* in the individual sera by a suitable method such as an immunochemical method (2.7.1) or neutralisation in cell cultures. Use a homologous reference serum calibrated in International Units of *C. novyi* alpha antitoxin. *Clostridia (multicomponent) rabbit antiserum BRP* is suitable for use as a reference serum. The vaccine complies with the test if the level of antibodies is not less than that found for a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species.

IDENTIFICATION

The vaccine stimulates the formation of novyi alpha antitoxin when injected into animals that do not have this antitoxin.

TESTS

Safety. Administer by a recommended route, to each of 2 sheep that have not been vaccinated against *C. novyi* (type B) twice the maximum dose of the vaccine stated on the label. Observe the animals for not less than 14 days. No abnormal local or systemic reaction occurs.

Residual toxicity. Inject 0.5 ml of the vaccine subcutaneously into each of 5 mice, each weighing 17 g to 22 g. Observe the animals for 7 days. No abnormal local or systemic reaction occurs.

Sterility. It complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Inject subcutaneously into each of not fewer than 10 healthy rabbits, 3 to 6 months old, a quantity of vaccine not exceeding the minimum dose stated on the label as the first dose. After 21 to 28 days, inject into the same animals a quantity of the vaccine not exceeding the minimum dose stated on the label as the second dose. 10 to 14 days after the second injection, bleed the rabbits and pool the sera.

The potency of the pooled sera is not less than 3.5 IU/ml.

The International Unit is the specific neutralising activity for *C. novyi* alpha toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of the pooled sera obtained from the rabbits is determined by comparing the quantity necessary to protect mice or other suitable animals against the toxic effects of a fixed dose of *C. novyi* alpha toxin with the quantity of a reference preparation of Clostridium novyi alpha antitoxin, calibrated in International Units, necessary to give the same protection. For this comparison, a suitable preparation of *C. novyi* alpha toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the reference preparation; the potency of the serum to be examined is determined in relation to the reference preparation using the test toxin.

Clostridia (multicomponent) rabbit antiserum BRP is suitable for use as a reference serum.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an approximately 5-day culture in liquid medium of *C. novyi* type B and dry by a suitable method. Select the test toxin by determining for mice the L₅₀/10 dose and the LD₅₀, the observation period being 72 h.

A suitable alpha toxin contains not less than one L₅₀/10 dose in 0.05 mg and not less than 10 LD₅₀ in each L₅₀/10 dose.

Determination of test dose of toxin. Prepare a solution of the reference preparation in a suitable liquid so that it contains 1 IU/ml. Prepare a solution of the test toxin in a suitable liquid so that 1 ml contains a precisely known amount such as 1 mg. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each mixture contains 1.0 ml of the solution of the reference preparation (1 IU), one of a series of graded volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice, each weighing 17 g to 22 g, for each mixture, inject a dose of 0.2 ml intramuscularly or subcutaneously into each mouse. Observe the mice for 72 h. If all the mice die, the amount of toxin present in 0.2 ml of the mixture is in excess of the test dose. If none of the mice die, the amount of toxin present in 0.2 ml of the mixture is less than the test dose. Prepare fresh mixtures such that 2.0 ml of each mixture contains 1.0 ml of the solution of the reference preparation (1 IU) and one of a series of graded volumes of the solution of the test toxin separated from each other by steps of not more than 20 per cent and covering the expected end-point. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than two mice for each mixture, inject a dose of 0.2 ml intramuscularly or subcutaneously into each mouse. Observe the mice for 72 h. Repeat the determination at least once and combine the results of the separate tests that have been made with mixtures of the same composition so that a series of totals is obtained, each total representing the mortality due to a mixture of a given composition.

The test dose of toxin is the amount present in 0.2 ml of that mixture which causes the death of one half of the total number of mice injected with it.

Determination of the potency of the serum obtained from rabbits

Preliminary test. Dissolve a quantity of the test toxin in a suitable liquid so that 1 ml contains 10 times the test dose (solution of the test toxin). Prepare a series of mixtures of the solution of the test toxin and of the serum to be examined such that each mixture contains 1.0 ml of the solution of the test toxin, one of a series of graded volumes of the serum to be examined and sufficient of a suitable liquid to bring the final volume to 2.0 ml. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.2 ml intramuscularly or subcutaneously into each mouse. Observe the mice for 72 h. If none of the mice dies, 0.2 ml of the mixture contains more than 0.1 IU. If all the mice die, 0.2 ml of the mixture contains less than 0.1 IU.

Final test. Prepare a series of mixtures of the solution of the test toxin and of the serum to be examined such that 2.0 ml of each mixture contains 1.0 ml of the solution of the test toxin and one of a series of graded volumes of the serum to be examined, separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined by the preliminary test. Prepare further mixtures of the solution of the test toxin and of the solution of the reference preparation such that 2.0 ml of each mixture contains 1.0 ml of the solution of the test toxin and one of a series of graded volumes of the solution of the reference

preparation, in order to confirm the test dose of the toxin. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, proceed as described in the preliminary test. The test mixture which contains 0.1 IU in 0.2 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing 0.1 IU in 0.2 ml. Repeat the determination at least once and calculate the average of all valid estimates. The test is valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits ($P = 0.95$) have been estimated to be:

- 85 per cent and 114 per cent when 2 animals per dose are used,
- 91.5 per cent and 109 per cent when 4 animals per dose are used,
- 93 per cent and 108 per cent when 6 animals per dose are used.

LABELLING

The label states:

- whether the product is a toxoid, a vaccine prepared from a whole inactivated culture or a mixture of the two,
- that the preparation is to be shaken before use,
- for each target species, the immunising effect produced (for example, antibody production, protection against signs of disease or infection).

CLOSTRIDIUM PERFRINGENS VACCINE FOR VETERINARY USE

Vaccinum clostridii perfringentis ad usum veterinarium

DEFINITION

Clostridium perfringens vaccine for veterinary use is prepared from liquid cultures of suitable strains of *Clostridium perfringens* type B, *C. perfringens* type C or *C. perfringens* type D or a mixture of these types.

PRODUCTION

The whole cultures or their filtrates or a mixture of the two are inactivated in such a manner that toxicity is eliminated and immunogenic activity is retained. Toxoids and/or inactivated cultures may be treated with a suitable adjuvant.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7). For the latter, it shall be demonstrated that for each target species the vaccine, when administered according to the recommended schedule, stimulates an immune response (for example, induction of antibodies) consistent with the claims made for the product.

BATCH TESTING

Residual toxicity. The test for residual toxicity may be omitted by the manufacturer, since a test for detoxification is carried out immediately after the detoxification process and, when there is risk of reversion, a second test is carried out at as late a stage as possible during the production process.

Batch potency test. The test described under Potency is not necessarily carried out for routine testing of batches of vaccine. It is carried out for a given vaccine on one or more occasions as decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable validated alternative test is carried out, the criteria

for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Vaccinate rabbits as described under Potency and prepare sera. Determine the level of antibodies against the beta and/or epsilon toxins of *C. perfringens* in the individual sera by a suitable method such as an immunochemical method (2.7.1) or neutralisation in cell cultures. Use a homologous reference serum calibrated in International Units of *C. perfringens* beta and/or epsilon antitoxin. *Clostridia (multicomponent) rabbit antiserum BRP* is suitable for use as a reference serum. The vaccine complies with the test if the level or levels of antibodies are not less than that found for a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species.

IDENTIFICATION

Type B. The vaccine stimulates the formation of beta and epsilon antitoxins when injected into animals that do not have these antitoxins.

Type C. The vaccine stimulates the formation of beta antitoxin when injected into animals that do not have this antitoxin.

Type D. The vaccine stimulates the formation of epsilon antitoxin when injected into animals that do not have this antitoxin.

TESTS

Safety. Use 2 animals of one of the species for which the vaccine is intended and that have not been vaccinated against *C. perfringens*. Administer by a recommended route to each animal, twice the maximum dose stated on the label. Observe the animals for 14 days. No abnormal local or systemic reaction occurs.

Residual toxicity. Inject 0.5 ml of the vaccine subcutaneously into each of 5 mice, each weighing 17 g to 22 g. Observe the animals for 7 days. No abnormal local or systemic reaction occurs.

Sterility. It complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

POTENCY

Inject subcutaneously into each of not fewer than 10 healthy rabbits, 3 to 6 months old, a quantity of vaccine not exceeding the minimum dose stated on the label as the first dose. After 21 to 28 days inject into the same animals a quantity of the vaccine not exceeding the minimum dose stated on the label as the second dose. 10 to 14 days after the second injection, bleed the rabbits and pool the sera.

Type B. The potency of the pooled sera is not less than 10 IU of beta antitoxin and not less than 5 IU of epsilon antitoxin per millilitre.

Type C. The potency of the pooled sera is not less than 10 IU of beta antitoxin per millilitre.

Type D. The potency of the pooled sera is not less than 5 IU of epsilon antitoxin per millilitre.

International standard for clostridium perfringens beta antitoxin

The International Unit is the specific neutralising activity for *C. perfringens* beta toxin contained in a stated amount of the International Standard which consists of a quantity of dried immune horse serum. The equivalence in International

Units of the International Standard is stated by the World Health Organisation.

International standard for clostridium perfringens epsilon antitoxin

The International Unit is the specific neutralising activity for *C. perfringens* epsilon toxin contained in a stated amount of the International Standard which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of the pooled sera obtained from the rabbits is determined by comparing the quantity necessary to protect mice or other suitable animals against the toxic effects of a fixed dose of *C. perfringens* beta toxin or *C. perfringens* epsilon toxin with the quantity of a reference preparation of clostridium perfringens beta antitoxin or clostridium perfringens epsilon antitoxin, as appropriate, calibrated in International Units, necessary to give the same protection. For this comparison, a suitable preparation of *C. perfringens* beta or epsilon toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the appropriate reference preparation; the potency of the serum to be examined is determined in relation to the appropriate reference preparation using the appropriate test toxin.

Clostridia (multicomponent) rabbit antiserum BRP is suitable for use as a reference serum.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an early culture in liquid medium of *C. perfringens* type B, type C or type D as appropriate and dry by a suitable method. Use a beta or epsilon toxin as appropriate. Select the test toxin by determining for mice the L+ and the LD₅₀ for the beta toxin and the L+/10 dose and the LD₅₀ for the epsilon toxin, the observation period being 72 h.

A suitable beta toxin contains not less than one L+ in 0.2 mg and not less than 25 LD₅₀ in one L+ dose. A suitable epsilon toxin contains not less than one L+/10 dose in 0.005 mg and not less than 20 LD₅₀ in one L+/10 dose.

Determination of test dose of toxin. Prepare a solution of the reference preparation in a suitable liquid so that it contains 5 IU/ml for clostridium perfringens beta antitoxin and 0.5 IU/ml for clostridium perfringens epsilon antitoxin. Prepare a solution of the test toxin in a suitable liquid so that 1 ml contains a precisely known amount such as 10 mg for beta toxin and 1 mg for epsilon toxin. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each contains 2.0 ml of the solution of the reference preparation, one of a series of graded volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice, each weighing 17 g to 22 g, for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. If all the mice die, the amount of toxin present in 0.5 ml of the mixture is in excess of the test dose. If none of the mice dies the amount of toxin present in 0.5 ml of the mixture is less than the test dose. Prepare fresh mixtures such that 5.0 ml of each mixture contains 2.0 ml of the solution of the reference preparation and one of a series of graded volumes of the solution of the test toxin separated from each other by steps of not more than 20 per cent and covering the expected end-point. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than two mice for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. Repeat the determination at least once and add together the results of the separate tests that

have been made with mixtures of the same composition so that a series of totals is obtained, each total representing the mortality due to a mixture of given composition.

The test dose of toxin is the amount present in 0.5 ml of that mixture which causes the death of one half of the total number of mice injected with it.

Determination of the potency of the serum obtained from rabbits

Preliminary test. Dissolve a quantity of the test toxin in a suitable liquid so that 2.0 ml contains 10 times the test dose (solution of the test toxin). Prepare a series of mixtures of the solution of the test toxin and of the serum to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a series of graded volumes of the serum to be examined and sufficient of a suitable liquid to bring the final volume to 5.0 ml. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. If none of the mice die, 0.5 ml of the mixture contains more than 1 IU of beta antitoxin or 0.1 IU of epsilon antitoxin. If all the mice die, 0.5 ml of the mixture contains less than 1 IU of beta antitoxin or 0.1 IU of epsilon antitoxin.

Final test. Prepare a series of mixtures of the solution of the test toxin and the serum to be examined such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the serum to be examined separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined by the preliminary test. Prepare further mixtures of the solution of the test toxin and of the solution of the reference preparation such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the solution of the reference preparation, in order to confirm the test dose of the toxin. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice for each mixture proceed as described in the preliminary test.

Beta antitoxin. The test mixture which contains 1 IU in 0.5 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing 1 IU in 0.5 ml.

Epsilon antitoxin. The test mixture which contains 0.1 IU in 0.5 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing 0.1 IU in 0.5 ml. Repeat the determination at least once and calculate the average of all valid estimates. The test is valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits ($P = 0.95$) have been estimated to be:

- 85 per cent and 114 per cent when 2 animals per dose are used,
- 91.5 per cent and 109 per cent when 4 animals per dose are used,
- 93 per cent and 108 per cent when 6 animals per dose are used.

LABELLING

The label states:

- the type or types of *C. perfringens* from which the vaccine has been prepared,
- whether the preparation is a toxoid or a vaccine prepared from a whole inactivated culture or a mixture of the two,
- that the preparation is to be shaken before use,

- for each target species, the immunising effect produced (for example, antibody production, protection against signs of disease or infection).

CLOSTRIDIUM SEPTICUM VACCINE FOR VETERINARY USE

Vaccinum clostridii septic ad usum veterinarium

DEFINITION

Clostridium septicum vaccine for veterinary use is prepared from a liquid culture of a suitable strain of *Clostridium septicum*.

PRODUCTION

The whole culture or its filtrate or a mixture of the two is inactivated in such a manner that toxicity is eliminated and immunogenic activity is retained. Toxoid and/or inactivated cultures may be treated with a suitable adjuvant.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7). For the latter, it shall be demonstrated that for each target species the vaccine, when administered according to the recommended schedule, stimulates an immune response (for example, induction of antibodies) consistent with the claims made for the product.

BATCH TESTING

Residual toxicity. The test for residual toxicity may be omitted by the manufacturer, since a test for detoxification is carried out immediately after the detoxification process and, when there is risk of reversion, a second test is carried out at as late a stage as possible during the production process.

Batch potency test. The test described under Potency is not necessarily carried out for routine testing of batches of vaccine. It is carried out for a given vaccine on one or more occasions as decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable validated alternative test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species. The following test may be used after a satisfactory correlation with the test described under Potency has been established. Vaccinate rabbits as described under Potency and prepare sera. Determine the level of antibodies against the toxin of *C. septicum* in the individual sera by a suitable method such as an immunochemical method (2.7.1) or neutralisation in cell cultures. Use a homologous reference serum calibrated in International Units of *C. septicum* antitoxin. *Clostridia (multicomponent) rabbit antiserum BRP* is suitable for use as a reference serum. The vaccine complies with the test if the level of antibodies is not less than that found for a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species.

IDENTIFICATION

The vaccine stimulates the formation of *C. septicum* antitoxin when injected into animals that do not have this antitoxin.

TESTS

Safety. Use 2 animals of one of the species for which the vaccine is intended and that have not been vaccinated against *C. septicum*. Administer to each animal, by a recommended route, twice the maximum dose stated on the label. Observe the animals for 14 days. No abnormal local or systemic reaction occurs.

Residual toxicity. Inject 0.5 ml of the vaccine subcutaneously into each of 5 mice, each weighing 17 g to 22 g. Observe the animals for 7 days. No abnormal local or systemic reaction occurs.

Sterility. It complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

POTENCY

Inject subcutaneously into each of not fewer than 10 healthy rabbits, 3 to 6 months old, a quantity of vaccine not exceeding the minimum dose stated on the label as the first dose. After 21 to 28 days, inject into the same animals a quantity of the vaccine not exceeding the minimum dose stated on the label as the second dose. 10 to 14 days after the second injection, bleed the rabbits and pool the sera.

The potency of the pooled sera is not less than 2.5 IU/ml.

The International Unit is the specific neutralising activity for *C. septicum* toxin contained in a stated amount of the International Standard which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of the pooled sera obtained from the rabbits is determined by comparing the quantity necessary to protect mice or other suitable animals against the toxic effects of a dose of *C. septicum* toxin with the quantity of a reference preparation of clostridium septicum antitoxin, calibrated in International Units, necessary to give the same protection. For this comparison, a suitable preparation of *C. septicum* toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the reference preparation; the potency of the serum to be examined is determined in relation to the reference preparation using the test toxin.

Clostridia (multicomponent) rabbit antiserum BRP is suitable for use as a reference serum.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of a 1- to 3-day culture of *C. septicum* in liquid medium and dry by a suitable method. Select the test toxin by determining for mice the $L_{+}/5$ dose and the LD_{50} the observation period being 72 h.

A suitable toxin contains not less than one $L_{+}/5$ dose in 1.0 mg and not less than 10 LD_{50} in each $L_{+}/5$ dose.

Determination of test dose of toxin. Prepare a solution of the reference preparation in a suitable liquid so that it contains 1.0 IU/ml. Prepare a solution of the test toxin in a suitable liquid so that 1 ml contains a precisely known amount, such as 4 mg. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each mixture contains 2.0 ml of the solution of the reference preparation (2 IU), one of a series of graded volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice, each weighing 17 g to 22 g, for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. If all the mice die, the amount of toxin present in 0.5 ml of the mixture is in excess of the test dose. If none of the mice die, the amount of toxin present in 0.5 ml of the mixture is less

than the test dose. Prepare fresh mixtures such that 5.0 ml of each mixture contains 2.0 ml of the reference preparation (2 IU) and one of a series of graded volumes of the solution of the test toxin separated from each other by steps of not more than 20 per cent and covering the expected end-point. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. Repeat the determination at least once and add together the results of the separate tests that have been made with mixtures of the same composition so that a series of totals is obtained, each total representing the mortality due to a mixture of a given composition.

The test dose of toxin is the amount present in 0.5 ml of that mixture which causes the death of one half of the total number of mice injected with it.

Determination of the potency of the serum obtained from rabbits

Preliminary test. Dissolve a quantity of the test toxin in a suitable liquid so that 2.0 ml contains ten times the test dose (solution of the test toxin). Prepare a series of mixtures of the solution of the test toxin and of the serum to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a series of graded volumes of the serum to be examined and sufficient of a suitable liquid to bring the final volume to 5.0 ml. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. If none of the mice dies, 0.5 ml of the mixture contains more than 0.2 IU. If all the mice die, 0.5 ml of the mixture contains less than 0.2 IU.

Final test. Prepare a series of mixtures of the solution of the test toxin and of the serum to be examined such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the serum to be examined, separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined by the preliminary test. Prepare further mixtures of the solution of the test toxin and of the solution of the reference preparation such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the solution of the reference preparation to confirm the test dose of the toxin. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture proceed as described in the preliminary test. The test mixture which contains 0.2 IU in 0.5 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing 0.2 IU in 0.5 ml. Repeat the determination at least once and calculate the average of all valid estimates. The test is valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits ($P = 0.95$) have been estimated to be:

- 85 per cent and 114 per cent when 2 animals per dose are used,
- 91.5 per cent and 109 per cent when 4 animals per dose are used,
- 93 per cent and 108 per cent when 6 animals per dose are used.

LABELLING

The label states:

- whether the preparation is a toxoid or a vaccine prepared from a whole inactivated culture, or a mixture of the two,
- that the preparation is to be shaken before use,

- for each target species, the immunising effect produced (for example, antibody production, protection against signs of disease or infection).

01/2005:0449

DISTEMPER VACCINE (LIVE) FOR MUSTELIDS, FREEZE-DRIED

*Vaccinum morbi Carrei vivum
cryodesiccatum ad mustelidas*

DEFINITION

Freeze-dried distemper vaccine (live) for mustelids is a preparation of a strain of distemper virus that is attenuated for ferrets.

PRODUCTION

The attenuated strain is grown in suitable cell cultures (5.2.4) or in fertilised hen eggs, obtained from healthy flocks.

CHOICE OF VACCINE STRAIN

Only a virus strain shown to be satisfactory with respect to attenuation and immunogenicity may be used in the preparation of the vaccine. The following tests may be used during demonstration of safety (5.2.6) and immunogenicity (5.2.7).

Attenuation. When a volume of a viral suspension equivalent to five doses of the vaccine is injected intramuscularly into each of two susceptible ferrets, it does not provoke pathogenic effects within 21 days.

Immunogenicity. The test described under Potency is suitable to demonstrate the immunogenicity of the strain.

BATCH TESTING

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot, subject to agreement by the competent authority.

IDENTIFICATION

The vaccine reconstituted as stated on the label and mixed with a specific distemper antiserum no longer provokes cytopathic effects in susceptible cell cultures or lesions on the chorio-allantoic membranes of fertilised hen eggs 9 to 11 days old.

TESTS

Safety. Inject by the route stated on the label twice the dose of the reconstituted vaccine into each of two susceptible ferrets free from distemper-virus-neutralising antibodies. Observe the animals for 21 days. They remain in normal health and no abnormal local or systemic reaction occurs.

Extraneous viruses. Mix the reconstituted vaccine with a monospecific antiserum. It no longer provokes cytopathic effects in susceptible cell cultures. It shows no evidence of haemagglutinating or haemadsorbing agents.

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

Mycoplasmas (2.6.7). The reconstituted vaccine complies with the test for mycoplasmas.

Virus titre. Titrate the reconstituted vaccine in suitable cell cultures or fertilised hen eggs 9 to 11 days old. One dose of the vaccine contains not less than the quantity of virus equivalent to the minimum titre stated on the label.

POTENCY

Use seven susceptible ferrets free from distemper-virus-neutralising antibodies. Vaccinate five of the ferrets according to the instructions for use. Keep the two other animals as controls. Observe all the animals for 21 days. Inject intramuscularly into each animal a quantity of distemper virus sufficient to cause the death of a susceptible ferret. Observe the animals for a further 21 days. The test is invalid if one or both of the control ferrets do not die of distemper. The vaccine complies with the test if the vaccinated ferrets remain in normal health.

01/2005:1315

DUCK VIRAL HEPATITIS TYPE I VACCINE (LIVE)

*Vaccinum hepatitis viralis anatis
stirpe I vivum*

1. DEFINITION

Duck viral hepatitis type I vaccine (live) is a preparation of a suitable strain of duck hepatitis virus type I. This monograph applies to vaccines intended for the active immunisation of breeder ducks in order to protect passively their progeny and/or for the active immunisation of ducklings.

2. PRODUCTION

2-1. PREPARATION OF THE VACCINE

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. SUBSTRATE FOR VIRUS PROPAGATION

2-2-1. Embryonated hens' eggs. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (5.2.2).

2-2-2. Cell cultures. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (5.2.4).

2-3. SEED LOTS

2-3-1. Extraneous agents. The master seed lot complies with the tests for extraneous agents in seed lots (2.6.24). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. CHOICE OF VACCINE VIRUS

The vaccine virus shall be shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) for the ducks for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during demonstration of safety and immunogenicity.

2-4-1. Safety. Carry out the test for each route and method of administration to be recommended for vaccination using in each case ducks not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test, use not fewer than 20 susceptible domestic ducklings (*Anas platyrhynchos*) that do not have antibodies against duck hepatitis virus type I. Administer to each duckling a quantity of vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of vaccine. Observe the ducklings at least daily for 21 days. The test is not valid if more than 10 per cent of the ducklings

die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no duckling shows notable signs of duck viral hepatitis or dies from causes attributable to the vaccine virus.

2-4-2. Increase in virulence. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of vaccine to a group of five 1-day-old domestic ducklings that do not have antibodies against duck hepatitis virus type I, sequential passages, 5 times where possible, to further similar groups of 1-day-old ducklings and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by the oro-nasal route a quantity of vaccine virus that will allow recovery of virus for the passages described below. 2 to 4 days later, take samples of liver from each duckling and pool the samples. Administer 1 ml of the pooled liver suspension by the oro-nasal route to each of five 1-day-old seronegative domestic ducklings. Carry out this operation 5 times. Verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Observe the ducklings given the last passage at least daily for 21 days. Compare the results obtained with unpassaged virus in the safety studies and those obtained with maximally passaged virus to assess the degree of increase in virulence. If the virus is not recovered at any passage level in the first and second series of passages, it is considered not to show increase in virulence.

2-4-3. Immunogenicity. A test is carried out for each route and method of administration to be recommended, using in each case domestic ducks not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each bird is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine.

2-4-3-1. Vaccines for passive immunisation of ducklings. Use for the test not fewer than 15 laying ducks or ducks intended for laying, as appropriate, of the same origin and that do not have antibodies against duck hepatitis virus type I. Vaccinate by a recommended route not fewer than 10 ducks using the schedule to be recommended. Maintain not fewer than 5 ducks as controls. Starting from 4 weeks after onset of lay, collect embryonated eggs from vaccinated and control ducks and incubate them. Challenge not fewer than twenty 1-week-old ducklings representative of the vaccinated group and not fewer than 10 from the control group by the oro-nasal route with a sufficient quantity of virulent duck hepatitis virus type I. Observe the ducklings at least daily for 14 days after challenge. Record the deaths and the number of surviving ducklings that show clinical signs of disease.

The test is not valid if:

- during the observation period after challenge fewer than 70 per cent of the challenged ducklings from the control ducks die or show typical signs of the disease,
- and/or during the period between vaccination and collection of the eggs more than 10 per cent of the control or vaccinated ducks show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge the percentage relative protection calculated using the following expression is not less than 80 per cent:

$$\frac{V - C}{100 - C} \times 100$$

- V* = percentage of challenged ducklings from vaccinated ducks that survive to the end of the observation period without clinical signs of the disease.
- C* = percentage of challenged ducklings from unvaccinated control ducks that survive to the end of the observation period without clinical signs of the disease.

2-4-3-2. Vaccines for active immunisation of ducklings. Use for the test not fewer than 30 ducklings of the same origin and that do not have antibodies against duck hepatitis virus type I. Vaccinate by a recommended route not fewer than 20 ducklings. Maintain not fewer than 10 ducklings as controls. Challenge each duckling after at least 5 days by the oro-nasal route with a sufficient quantity of virulent duck hepatitis virus type I. Observe the ducklings at least daily for 14 days after challenge. Record the deaths and the number of surviving ducklings that show clinical signs of disease.

The test is not valid if:

- during the observation period after challenge fewer than 70 per cent of the control ducklings die or show typical signs of the disease,
- and/or during the period between vaccination and challenge more than 10 per cent of the control or vaccinated ducklings show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge the percentage relative protection calculated using the following expression is not less than 80 per cent:

$$\frac{V - C}{100 - C} \times 100$$

- V* = percentage of challenged vaccinated ducklings that survive to the end of the observation period without clinical signs of the disease.
- C* = percentage of challenged unvaccinated control ducklings that survive to the end of the observation period without clinical signs of the disease.

3. BATCH TESTS

3-1. Identification. The vaccine, diluted if necessary and mixed with a monospecific duck hepatitis virus type I antiserum, no longer infects embryonated hens' eggs from an SPF flock (5.2.2) or susceptible cell cultures (5.2.4) into which it is inoculated.

3-2. Bacteria and fungi

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for

micro-organisms detected in the vaccine; the vaccine does not contain pathogenic micro-organisms and contains not more than 1 non-pathogenic micro-organism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062).

3-3. Mycoplasmas. The vaccine complies with the test for mycoplasmas (2.6.7).

3-4. Extraneous agents. The vaccine complies with the tests for extraneous agents in batches of finished product (2.6.25).

3-5. Safety. Use not fewer than 10 domestic ducks that do not have antibodies against duck hepatitis virus type I and of the youngest age recommended for vaccination. For vaccines recommended for use in ducks older than 2 weeks, ducks 2 weeks old may be used. Administer by a recommended route and method to each duck 10 doses of the vaccine. Observe the ducks at least daily for 21 days. The test is not valid if more than 20 per cent of ducks show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no duck shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. Virus titre. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (5.2.2) or into suitable cell cultures (5.2.4). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. Potency. Depending on the indications, the vaccine complies with 1 or both of the tests prescribed under Immunogenicity (section 2-4-3), when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

4. LABELLING

If it has been found that the vaccine may show reversion to virulence, the label indicates the precautions necessary to avoid transmission of virulent virus to unvaccinated ducklings.

01/2005:1202

EGG DROP SYNDROME '76 VACCINE (INACTIVATED)

*Vaccinum morbi partus diminutionis
MCMLXXVI inactivatum ad pullum*

DEFINITION

Egg drop syndrome '76 vaccine (inactivated) consists of an emulsion or a suspension of a suitable strain of egg drop syndrome '76 virus (haemagglutinating avian adenovirus) which has been inactivated in such a manner that immunogenic activity is retained.

PRODUCTION

The vaccine strain is propagated in fertilised hen or duck eggs from healthy flocks or in suitable cell cultures (5.2.4).

The test for inactivation is carried out in fertilised duck eggs from a flock free from egg drop syndrome '76 virus infection or hen eggs from a flock free from specified pathogens

(5.2.2), or in suitable cell cultures, whichever is the most sensitive for the vaccine strain; the quantity of virus used in the test is equivalent to not less than ten doses of the vaccine. No live virus is detected.

The vaccine may contain adjuvants.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety and immunogenicity. The following test may be used during demonstration of efficacy (5.2.7).

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity.

BATCH TESTING

The test described under Potency is not necessarily carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Batch potency test. Vaccinate not fewer than ten 14- to 28-day-old chickens from a flock free from specified pathogens (5.2.2) with one dose of vaccine by one of the recommended routes. Four weeks later, collect serum samples from each bird and from five unvaccinated control birds of the same age and from the same source. Measure the antibody response in a haemagglutination (HA) inhibition test on each serum using four HA units of antigen and chicken erythrocytes. The test is not valid if there are specific antibodies in the sera of the unvaccinated birds. The vaccine complies with the test if the mean titre of the vaccinated group is not less than that found previously for a batch of vaccine that has given satisfactory results in the test described under Potency.

IDENTIFICATION

In chickens with no antibodies to egg drop syndrome '76 virus, the vaccine stimulates the production of specific antibodies.

TESTS

Safety. Inject a double dose by a recommended route into each of 10 chickens, 14 to 28 days old, from a flock free from specified pathogens (5.2.2). Observe the birds for 21 days. No abnormal local or systemic reaction occurs.

Inactivation

A. For a vaccine prepared in eggs, carry out the test in fertilised duck eggs from a flock free from egg drop syndrome '76 virus infection or, if it is known to provide a more sensitive test system, in hen eggs from a flock free from specified pathogens (5.2.2).

Inject two-fifths of a dose into the allantoic cavity of each of ten 10- to 14-day-old fertilised eggs that are free from parental antibodies to egg drop syndrome '76 virus. Incubate the eggs and observe for 8 days. Pool separately the allantoic fluid from eggs containing live embryos, and that from eggs containing dead embryos, excluding those that die from non-specific causes within 24 h of the injection.

Inject into the allantoic cavity of each of ten 10- to 14-day-old fertilised eggs that are free from parental antibodies to egg drop syndrome '76 virus, 0.2 ml of the pooled allantoic fluid from the live embryos and into each of ten similar eggs, 0.2 ml of the pooled allantoic fluid

from the dead embryos and incubate for 8 days. Examine the allantoic fluid from each egg for the presence of haemagglutinating activity using chicken erythrocytes.

If more than 20 per cent of the embryos die at either stage, repeat that stage. The vaccine complies with the test if there is no evidence of haemagglutinating activity and if, in any repeat test, not more than 20 per cent of the embryos die from non-specific causes.

Antibiotics may be used in the test to control extraneous bacterial infection.

- B. For a vaccine adapted to growth in cell cultures, inoculate ten doses into suitable cell cultures. If the vaccine contains an oily adjuvant, eliminate it by suitable means. Incubate the cultures at $38 \pm 1^\circ\text{C}$ for 7 days. Make a passage on another set of cell cultures and incubate at $38 \pm 1^\circ\text{C}$ for 7 days. Examine the cultures regularly and at the end of the incubation period examine the supernatant liquid for the presence of haemagglutinating activity. The vaccine complies with the test if the cell cultures show no sign of infection and if there is no haemagglutinating activity in the supernatant liquid.

Extraneous agents. Use the chickens from the test for safety. 21 days after injection of the double dose of vaccine, inject one dose by the same route into each chicken. Collect serum samples from each chicken 2 weeks later and carry out tests for antibodies to the following agents by the methods prescribed for chicken flocks free from specified pathogens (5.2.2): avian encephalomyelitis virus, avian leucosis viruses, infectious bronchitis virus, infectious bursal disease virus, infectious laryngotracheitis virus, influenza A virus, Marek's disease virus, Newcastle disease virus and, for vaccine produced in duck eggs, *Chlamydia* (by a complement-fixation test or agar gel precipitation test), duck hepatitis virus type I (by a fluorescent-antibody test or serum-neutralisation test) and Derzsy's disease virus (by a serum-neutralisation test). The vaccine does not stimulate the formation of antibodies against these agents.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Vaccinate each of 2 groups of 30 hens from a flock free from specified pathogens (5.2.2) and of the age at which vaccination is recommended. Maintain two control groups one of 10 hens and the other of 30 hens, of the same age and from the same source as the vaccinates. Keep individual egg production records from point of lay until 4 weeks after challenge.

At 30 weeks of age, 1 group of 30 vaccinates and the group of 10 control birds are challenged with a dose of egg drop syndrome '76 virus sufficient to cause a well marked drop in egg production and/or quality. The vaccine complies with the test if the vaccinated birds show no marked drop in egg production and/or quality. The test is not valid unless there is a well marked drop in egg production and/or quality in the control birds.

When the second group of vaccinated birds and the group of 30 control birds are nearing the end of lay, challenge these birds, as before. The vaccine complies with the test if the vaccinated birds show no marked drop in egg production and/or quality. The test is not valid unless there is a well marked drop in egg production and/or quality in the control birds.

Carry out serological tests on serum samples obtained at the time of vaccination, 4 weeks later and just prior to challenge. The test is not valid if antibodies to egg drop syndrome '76 virus are detected in any sample from control birds.

LABELLING

The label states whether the strain in the vaccine is duck- or hen-embryo-adapted or cell-culture-adapted.

01/2005:1613

EQUINE HERPESVIRUS VACCINE (INACTIVATED)

Vaccinum herpesvirus equini inactivatum

DEFINITION

Equine herpesvirus vaccine (inactivated) is a preparation of one or more suitable strains of equid herpesvirus 1 and/or equid herpesvirus 4 inactivated without impairing their immunogenic activity or a suspension of an inactivated fraction of the virus.

PRODUCTION

Each strain of virus is propagated separately in suitable cell cultures (5.2.4). The viral suspensions may be purified and concentrated and are inactivated; they may be treated to fragment the virus and the viral fragments may be purified and concentrated.

The test for residual infectious equid herpesvirus is carried out using 2 passages in the same type of cell culture as that used in the production or in cell cultures shown to be at least as sensitive. The quantity of inactivated virus used in the test is equivalent to not less than 25 doses of the vaccine. No live virus is detected.

The vaccine may contain a suitable adjuvant.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and immunogenicity (5.2.7) in horses. Where a particular breed of horse is known to be especially sensitive to the vaccine, horses from that breed are included in the test for safety. The following tests may be used during demonstration of safety and immunogenicity.

Safety. A test is carried out in each category of animals for which the vaccine is intended and by each recommended route. 2 doses of vaccine are administered to each of not fewer than 10 animals which have not been previously vaccinated with an equine herpesvirus vaccine, which have at most a low antibody titre not indicative of recent infection and which do not excrete equid herpesvirus. After 14 days, 1 dose of vaccine is injected into each of the animals. The animals are observed for a further 14 days. During the 28 days of the test, no abnormal or systemic reaction occurs. If the vaccine is intended for use in pregnant horses, for the test in this category of animal, mares are vaccinated during the relevant trimester or trimesters of pregnancy and the observation period is prolonged up to foaling; any effects on gestation or the offspring are noted.

Immunogenicity. The claims of the product reflect the type of immunogenicity demonstrated (protection against the disease of the respiratory tract and/or protection against abortion). The tests described under Potency are suitable to demonstrate the immunogenicity of the strains present in the vaccine.

BATCH TESTING

The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine on one or more occasions; where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the tests described under Potency. The following test may be used.

Batch potency test. Vaccinate not fewer than 5 rabbits, guinea-pigs or mice with a single injection of a suitable dose. Where the schedule stated on the label requires a second injection to be given, the recommended schedule may be used in laboratory animals provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval within the range of 14 to 21 days after the last injection, collect blood from each animal and prepare serum samples. Use a suitable validated test such as an enzyme-linked immunosorbent assay to measure the response to each of the antigens stated on the label. The antibody levels are not significantly less than those obtained with a batch that has given satisfactory results in the test described under Potency.

IDENTIFICATION

In animals having no antibodies against equid herpesvirus 1 and equid herpesvirus 4 or a fraction of the viruses, the vaccine stimulates the production of specific antibodies against the virus type or types included in the product. The method used must distinguish between antibodies against equid herpesviruses 1 and 4.

TESTS

Safety. Use for the test horses that have not been vaccinated against equid herpesviruses 1 and 4. Administer by a recommended route twice the vaccinating dose into each of not fewer than 2 horses. After 2 weeks, administer a single dose to each of the animals. Observe the animals for a further 10 days. The animals remain in good health and no abnormal local or systemic reaction occurs.

Inactivation. Carry out a test for residual infectious equid herpesvirus using not less than 25 doses of vaccine by inoculating cell cultures sensitive to equid herpesviruses 1 and 4; make a passage after 5 to 7 days and maintain the cultures for 14 days. No live virus is detected. If the vaccine contains an adjuvant, separate the adjuvant from the liquid phase, by a method that does not inactivate or otherwise interfere with the detection of live virus, or carry out a test for inactivation on the mixture of bulk antigens before addition of the adjuvant.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

The type of potency test depends on the claims for the product. For vaccines intended to protect against the disease of the respiratory tract carry out test A, using equid herpesvirus 1 and/or equid herpesvirus 4 depending on the claims for protection. For vaccines intended to protect against abortion carry out test B.

Use horses which have not been vaccinated with an equine herpesvirus vaccine, which have at most a low antibody titre not indicative of recent infection, and which do not excrete equid herpesvirus. To demonstrate that no recent infection occurs, immediately before vaccination: draw a blood sample from each animal and test individually for antibodies against equid herpesviruses 1 and 4; collect 10 ml of heparinised blood and test the washed leucocytes for equid

herpesviruses 1 and 4; collect a nasopharyngeal swab and test for equid herpesviruses 1 and 4. There is no indication of an active infection. Immediately before challenge collect a nasopharyngeal swab and test for equid herpesviruses 1 and 4. If there is an indication of virus excretion remove the animal from the test. Keep the horses in strict isolation.

- A. Use not fewer than 10 horses, not less than 6 months old. Vaccinate not fewer than 6 horses using the recommended schedule. Keep not fewer than 4 unvaccinated horses as controls. At least 2 weeks after the last vaccination, administer by nasal instillation to all horses a quantity of equid herpesvirus 1 or 4, sufficient to produce in a susceptible horse characteristic signs of the disease such as pyrexia and virus excretion (and possibly nasal discharge and coughing). Observe the horses for 14 days. Collect nasopharyngeal swabs daily from each individual animal to isolate the virus. The vaccinated horses show no more than slight signs; the signs in vaccinates are less severe than in controls. The average number of days on which virus is excreted, and the respective virus titres are significantly lower in vaccinated horses than in controls.
- B. Use not fewer than 10 pregnant mares. In addition to the testing described above, 6, 4, 3, 2 and 1 month before the first vaccination draw a blood sample from each horse and test individually for antibodies against equid herpesvirus 1 and equid herpesvirus 4. There is no evidence of recent infection or virus excretion. Vaccinate not fewer than 6 mares using the recommended schedule. Keep not fewer than 4 horses as unvaccinated controls. Between day 260 and 290 of pregnancy but not earlier than 3 weeks after the last vaccination administer by nasal instillation to all horses a quantity of equid herpesvirus 1 sufficient to produce abortion in susceptible mares. Observe the mares up to foaling or abortion. Collect samples of fetal lung and liver tissues from aborted fetuses and carry out tests for virus in cell cultures. The test is invalid if more than one control horse gives birth to a healthy foal and if the challenge virus is not isolated from the aborted fetuses. The vaccine complies with the test if not more than one vaccinated mare aborts.

LABELLING

The label states:

- the strains of virus included in the vaccine,
- the claims of protection.

01/2005:0249
corrected

EQUINE INFLUENZA VACCINE (INACTIVATED)

Vaccinum influenzae equi inactivatum

DEFINITION

Equine influenza vaccine (inactivated) is a preparation of one or more suitable strains of equine influenza virus, inactivated in such a manner that immunogenic activity is maintained. Suitable strains contain both haemagglutinin and neuraminidase.

PRODUCTION

Each strain of virus is propagated separately in fertilised hen eggs from healthy flocks or in suitable cell cultures (5.2.4). The viral suspensions may be purified and concentrated. The antigen content of the vaccine is based on the haemagglutinin content of the viral suspensions

determined as described under In-process Tests; the amount of haemagglutinin for each strain is not less than that in the vaccine shown to be satisfactory in the test for potency.

The test for residual infectious influenza virus is carried out using method A or method B whichever is the more sensitive. The quantity of inactivated virus used is equivalent to not less than 10 doses of vaccine.

- A. The vaccine is inoculated into suitable cells; after incubation for 8 days, a subculture is made. It is incubated for a further 6 to 8 days. Harvest about 0.1 ml of the supernatant and examine for live virus by a haemagglutination test. If haemagglutination is found, carry out a further passage in cell culture and test for haemagglutination; no haemagglutination occurs.
- B. Inoculate 0.2 ml into the allantoic cavity of each of 10 fertilised eggs and incubate at 33 °C to 37 °C for 3 to 4 days. The test is not valid unless not fewer than 8 of the 10 embryos survive. Harvest 0.5 ml of the allantoic fluid from each surviving embryo and pool the fluids. Inoculate 0.2 ml of the pooled fluid into a further 10 fertilised eggs and incubate at 33 °C to 37 °C for 3 to 4 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest about 0.1 ml of the allantoic fluid from each surviving embryo and examine each individual harvest for live virus by a haemagglutination test. If haemagglutination is found for any of the fluids, carry out a further passage of that fluid in eggs and test for haemagglutination; no haemagglutination occurs.

The vaccine may contain suitable adjuvants.

CHOICE OF VACCINE COMPOSITION

The choice of strains used in the vaccine is based on epidemiological data. The Office international des épizooties reviews the epidemiological data periodically and if necessary recommends new strains corresponding to prevailing epidemiological evidence. Such strains are used in accordance with the regulations in force in the signatory States of the Convention on the Elaboration of a European Pharmacopoeia.

The vaccine is shown to be satisfactory with respect to safety and immunogenicity in horses. Where a particular breed of horse is known to be especially sensitive to the vaccine, horses from that breed are included in the tests for safety. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Safety. A test is carried out in each category of animals for which the vaccine is intended and by each recommended route. Use animals that preferably have no equine influenza antibodies or, where justified, use animals with a low level of such antibodies as long as they have not been vaccinated against equine influenza and administration of the vaccine does not cause an anamnestic response. 2 doses of vaccine are injected by the intended route into each of not fewer than 10 animals. After 14 days, 1 dose of vaccine is injected into each of the animals. The animals are observed for a further 14 days. During the 28 days of the test, no abnormal local or systemic reaction occurs. If the vaccine is intended for use in pregnant horses, for the test in this category of animal, horses are vaccinated during the relevant trimester or trimesters of pregnancy and the observation period is prolonged up to foaling; any effects on gestation or the offspring are noted.

Immunogenicity. The test described under Potency is suitable to demonstrate the immunogenicity of the strains present in the vaccine.

A test with virulent challenge is carried out for at least one vaccine strain. For other strains in the vaccine, demonstration of immunogenicity may, where justified, be

based on the serological response induced in horses by the vaccine; justification for protection against these strains may be based on published data on the correlation of the antibody titre with protection against antigenically related strains.

Where serology is used, the test is carried out as described under Potency but instead of virulent challenge, a blood sample is drawn 2 weeks after the last vaccination and the antibody titre of each serum is determined by a suitable immunochemical method (2.7.1), such as the single radial haemolysis test or the haemagglutination-inhibition test shown below; a reference serum is used to validate the test. The acceptance criteria depend on the strain and are based on available data; for A/equine-2 virus, vaccines have usually been found satisfactory if the antibody titre of each serum is not less than 85 mm² where the single radial haemolysis test is used, or not less than 1:64 (before mixture with the suspension of antigen and erythrocytes) where the haemagglutination-inhibition test is used.

Equine influenza subtype 1 horse antiserum BRP, equine influenza subtype 2 American-like horse antiserum BRP and equine influenza subtype 2 European-like horse antiserum BRP are suitable for use as reference sera for the single radial haemolysis test.

The claims for the product reflect the type of immunogenicity demonstrated (protection against challenge or antibody production).

Single radial haemolysis. Heat each serum at 56 °C for 30 min. Perform tests on each serum using respectively the antigen or antigens prepared from the strain(s) used in the production of the vaccine. Mix 1 ml of sheep erythrocyte suspension in barbital buffer solution (1 volume of erythrocytes in 10 volumes of final suspension) with 1 ml of a suitable dilution of the influenza virus strain in barbital buffer solution and incubate the mixture at 4 °C for 30 min. To 2 ml of the virus/erythrocyte mixture, add 1 ml of a 3 g/l solution of *chromium(III) chloride hexahydrate R*, mix and allow to stand for 10 min. Heat the sensitised erythrocytes to 47 °C in a water-bath. Mix 15 ml of a 10 g/l solution of *agarose for electrophoresis R* in barbital buffer solution, 0.7 ml of sensitised erythrocyte suspension and the appropriate amount of diluted guinea-pig complement in barbital buffer solution at 47 °C. Pour the mixture into Petri dishes and allow the agar to set. Punch holes in the agar layer and place in each hole, 5 µl of the undiluted serum to be tested or control serum. Incubate the Petri dishes at 37 °C for 18 h. Measure the diameter of the haemolysis zone and calculate its area, which expresses the antibody titre, in square millimetres.

Equine influenza subtype 1 horse antiserum BRP, equine influenza subtype 2 American-like horse antiserum BRP and equine influenza subtype 2 European-like horse antiserum BRP are suitable for use as reference sera for the single radial haemolysis test.

Haemagglutination-inhibition test. Inactivate each serum by heating at 56 °C for 30 min. To one volume of each serum add three volumes of *phosphate-buffered saline pH 7.4 R* and four volumes of a 250 g/l suspension of *light kaolin R* in the same buffer solution. Shake each mixture for 10 min. Centrifuge, collect the supernatant liquid and mix with a concentrated suspension of chicken erythrocytes. Allow to stand at 37 °C for 60 min and centrifuge. The dilution of the serum obtained is 1:8. Perform tests on each serum using each antigen prepared from the strains used in the production of the vaccine. Using each diluted serum, prepare a series of twofold dilutions. To 0.025 ml of each of the latter dilutions add 0.025 ml of a suspension of antigen treated with *ether R* and containing four haemagglutinating units. Allow the mixture to stand for 30 min and add 0.05 ml of a suspension

of chicken erythrocytes containing 2×10^7 erythrocytes/ml. Allow to stand for 1 h and note the last dilution of serum that still completely inhibits haemagglutination.

IN-PROCESS TESTS

The content of haemagglutinin in the inactivated virus suspension, after purification and concentration where applicable, is determined by a suitable immunochemical method (2.7.1), such as single radial immunodiffusion, using a suitable haemagglutinin reference preparation; the content is shown to be within the limits shown to allow preparation of a satisfactory vaccine. For vaccines produced in eggs, the content of bacterial endotoxins is determined on the virus harvest to monitor production.

BATCH TESTING

The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Batch potency test. Inject one dose of vaccine subcutaneously into each of 5 guinea-pigs free from specified antibodies. 21 days later, collect blood samples and separate the serum. Carry out tests on the serum for specific antibodies by a suitable immunochemical method (2.7.1) such as single radial haemolysis or haemagglutinin inhibition, using reference sera to validate the test. The antibody titres are not significantly lower than those obtained in guinea-pigs with a reference batch of vaccine shown to have satisfactory potency in horses.

IDENTIFICATION

In susceptible animals, the vaccine stimulates the production of specific antibodies.

TESTS

Safety. Use horses that preferably have no equine influenza virus antibodies or, where justified, use horses with a low level of such antibodies as long as they have not been vaccinated against equine influenza and administration of the vaccine does not cause an anamnestic response. Administer by a recommended route a double dose of vaccine to each of not fewer than 2 horses. After 2 weeks, administer a single dose to each horse. Observe the animals for a further 10 days. No abnormal local or systemic reaction occurs.

Inactivation. Inoculate 0.2 ml of the vaccine into the allantoic cavity of each of 10 fertilised eggs and incubate at 33 °C to 37 °C for 3 to 4 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest 0.5 ml of the allantoic fluid from each surviving embryo and pool the fluids. Inoculate 0.2 ml of the pooled fluid into a further 10 fertilised eggs and incubate at 33 °C to 37 °C for 3 to 4 days. The test is not valid unless not fewer than 8 of the 10 embryos survive. Harvest about 0.1 ml of the allantoic fluid from each surviving embryo and examine each individual harvest for live virus by a haemagglutination test. If haemagglutination is found for any of the fluids, carry out for that fluid a further passage in eggs and test for haemagglutination; no haemagglutination occurs.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Carry out the potency test using a challenge strain against which the vaccine is stated to provide protection. Use where possible a recent isolate.

Use 10 horses, at least 6 months old, that do not have specific antibodies against equine influenza virus. Draw a blood sample from each animal and test individually for antibodies against equine influenza virus to determine seronegativity. Vaccinate 6 animals using the recommended schedule. Draw a second blood sample from each animal 7 days after the first vaccination and test individually for antibodies against equine influenza virus, to detect an anamnestic sero-response. Animals showing sero-conversion at this stage are excluded from the test. At least 2 weeks after the last vaccination, administer by aerosol to the 10 animals a quantity of equine influenza virus sufficient to produce characteristic signs of disease such as fever, nasal discharge and coughing in a susceptible animal. Observe the animals for 14 days. Collect nasal swabs daily from each individual animal to isolate the virus. The vaccinated animals show no more than slight signs; the controls show characteristic signs. The average number of days on which virus is excreted, and the respective virus titres are significantly lower in vaccinated animals than in control animals.

LABELLING

The label states:

- the age at which animals should be vaccinated,
- the period of time that should elapse between the first and second injections,
- any booster injections required,
- the strains of virus included in the vaccine.

01/2005:1101

FELINE CALICIVIROSI VACCINE (INACTIVATED)

Vaccinum calicivirosis felinae inactivatum

DEFINITION

Inactivated feline calicivirus vaccine is a suspension of one or more suitable strains of feline calicivirus which have been inactivated while maintaining adequate immunogenic properties or of fractions of one or more strains of feline calicivirus with adequate immunogenic properties.

PRODUCTION

The virus is grown in suitable cell lines (5.2.4). The viral suspension is harvested and inactivated.

The test for residual infectious calicivirus is carried out using 2 passages in cell cultures of the same type as those used for preparation of the vaccine or in cell cultures shown to be at least as sensitive; the quantity of inactivated virus used in the test is equivalent to not less than 25 doses of vaccine. No live virus is detected.

The vaccine may contain one or more suitable adjuvants.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety and immunogenicity in cats. The following test may be used during demonstration of efficacy (5.2.7).

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity of the vaccine.

BATCH TESTING

Batch potency test. *The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated alternative test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established.*

Use groups of 15 seronegative mice. Administer half a dose of the vaccine to each mouse and 7 days later repeat the administration. 21 days after the first injection, take blood samples and determine the level of antibodies against feline calicivirus by an immunofluorescence technique using pools of serum from groups of 3 mice. The antibody levels are not significantly lower than those obtained with a batch of vaccine that has given satisfactory results in the test described under Potency.

IDENTIFICATION

When injected into susceptible animals, the vaccine stimulates the formation of specific antibodies against feline calicivirus.

TESTS

Safety. Use cats 8 to 12 weeks old and preferably having no feline calicivirus antibodies or, where justified, use cats with a low level of such antibodies as long as they have not been vaccinated against feline calicivirus and administration of the vaccine does not cause an anamnestic response. Administer a double dose of vaccine by a recommended route to each of 2 cats. Observe the cats for 14 days. No abnormal local or systemic reaction occurs.

Inactivation. Carry out a test for residual infectious calicivirus using 10 doses of vaccine and 2 passages in cell cultures of the same type as those used for preparation of the vaccine or in cell cultures shown to be at least as sensitive. No live virus is detected. If the vaccine contains an adjuvant that would interfere with the test, where possible separate the adjuvant from the liquid phase by a method that does not inactivate or otherwise interfere with detection of live virus.

Sterility. The reconstituted vaccine complies with the test for sterility prescribed in *Vaccines for veterinary use (0062)*.

POTENCY

Carry out a potency test for each strain of feline calicivirus in the vaccine.

Use cats 8 to 12 weeks old and that do not have antibodies against feline calicivirus. Vaccinate 10 cats by a recommended route and according to the recommended schedule. Keep 10 cats as controls. 4 weeks after the last injection, administer intranasally to each vaccinated and control cat a quantity of a virulent strain of calicivirus of the same type as the vaccine strain sufficient to produce typical signs of the disease (hyperthermia, buccal ulcers, respiratory signs) in at least 8 of the control cats. Observe the cats for 14 days after challenge; collect nasal washings daily on days 2 to 14 to test for virus excretion. Note daily the body temperature and signs of disease using the scoring system shown below. The vaccine complies with the test if the score for the vaccinated cats is significantly lower than that for the controls.

Observed signs	Score
Death	10
Depressed state	2
Temperature ≥ 39.5 °C	1
Temperature ≤ 37 °C	2
Ulcer (nasal or oral)	
– small and few in number	1
– large and numerous	3
Nasal discharge	
– slight	1
– copious	2
Ocular discharge	1

Virus excretion (total number of days):	
≤ 4 days	1
5-7 days	2
>7 days	3

01/2005:1102

FELINE CALICIVIROSI VACCINE (LIVE), FREEZE-DRIED

Vaccinum calicivirosi felinae vivum
cryodesiccatum

DEFINITION

Freeze-dried feline calicivirus vaccine (live) is a preparation of one or more suitable strains of feline calicivirus.

PRODUCTION

The virus is grown in suitable cell lines (5.2.4). The viral suspension is harvested and mixed with a suitable stabilising solution. The mixture is subsequently freeze-dried.

CHOICE OF VACCINE STRAIN

The vaccine strain shall have been shown to be satisfactory with respect to safety (including safety for pregnant queens if such use is not contra-indicated), absence of reversion to virulence, and immunogenicity. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Safety. To 10 cats of the minimum age stated for vaccination and which do not have antibodies against feline calicivirus, administer by a recommended route, a quantity of virus equivalent to 10 times the maximum titre that may be expected in a batch of vaccine. Observe the cats for 21 days. No abnormal local or systemic reaction occurs.

Reversion to virulence. To 2 cats which do not have antibodies against feline calicivirus administer by a recommended route a quantity of virus (for example, approximately 10 doses) that will allow maximum recovery of virus for the passages described below. 5 days later, kill the cats, remove the nasal mucus, tonsils and the trachea, mix, homogenise in 10 ml of buffered saline and decant; inoculate the supernatant intranasally into 2 other cats; carry out this operation five times. Verify the presence of virus at each passage. If the virus is not recovered, carry out a second series of passages. Observe the cats given the last passage for 21 days and compare the reactions observed with

those seen in the cats in the safety test described above. The strain complies with the test if no evidence of an increase in virulence is seen compared to the original virus.

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity.

BATCH TESTING

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot, subject to agreement by the competent authority.

IDENTIFICATION

When neutralised by one or more monospecific antisera, the reconstituted vaccine no longer infects susceptible cell cultures into which it is inoculated.

TESTS

Safety. Administer 10 doses of vaccine, by a recommended route to 2 cats, 8 to 12 weeks old and having no antibodies against feline calicivirus. Observe the cats for 14 days. No abnormal local or systemic reaction occurs.

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility prescribed in *Vaccines for veterinary use (0062)*.

Mycoplasmas (2.6.7). The reconstituted vaccine complies with the test for mycoplasmas.

Extraneous viruses. Neutralise the vaccine using one or more monospecific antisera and inoculate into suitable cell cultures; make at least one passage and maintain the cultures for 14 days. Examine the cultures for cytopathic effects and carry out tests for haemadsorbing agents. No signs of viral contamination occur in the cell cultures.

Virus titre. Titrate the reconstituted vaccine in susceptible cell cultures at a temperature favourable to replication of the virus. One dose of the vaccine contains not less than the quantity of virus equivalent to the minimum titre stated on the label.

POTENCY

Carry out a potency test for each strain of feline calicivirus in the vaccine.

Use cats 8 to 12 weeks old that do not have antibodies against feline calicivirus. Vaccinate 10 cats by one of the recommended routes and according to the recommended schedule. Keep 10 cats as controls. 4 weeks after the last injection, administer intranasally to each vaccinated and control cat a quantity of a virulent strain of calicivirus of the same type as the vaccine strain sufficient to produce typical signs of the disease (hyperthermia, buccal ulcers, respiratory signs) in not fewer than 8 of the control cats. Observe the cats for 14 days after challenge; collect nasal washings daily on days 2 to 14 to test for virus excretion. Note daily the body temperature and signs of disease using the scoring system shown below. The vaccine complies with the test if the score for the vaccinated cats is significantly lower than that for the controls.

Observed signs	Score
Death	10
Depressed state	2
Temperature ≥ 39.5 °C	1
Temperature ≤ 37 °C	2
Ulcer (nasal or oral)	
– small and few in number	1
– large and numerous	3

01/2005:0794

**FELINE INFECTIOUS ENTERITIS
(FELINE PANLEUCOPENIA) VACCINE
(INACTIVATED)**

*Vaccinum panleucopeniae felinae infectivae
inactivatum*

DEFINITION

Feline infectious enteritis (feline panleucopenia) vaccine (inactivated) is a liquid or freeze-dried preparation of feline panleucopenia virus or canine parvovirus inactivated by a suitable method.

PRODUCTION

The virus is propagated in suitable cell cultures (5.2.4). The virus is harvested and may be purified and concentrated.

The test for inactivation is carried out using a quantity of inactivated virus equivalent to not less than 100 doses of the vaccine by a validated method such as the following: inoculate into suitable non-confluent cells and after incubation for 8 days, make a subculture using trypsinised cells. After incubation for a further 8 days, examine the cultures for residual live parvovirus by an immunofluorescence test. The immunofluorescence test may be supplemented by a haemagglutination test or other suitable tests on the supernatant of the cell cultures. No live virus is detected.

The vaccine may contain an adjuvant and may be freeze-dried.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) in cats. The following test may be used during demonstration of immunogenicity.

Immunogenicity. Use 10 susceptible cats, 8 to 12 weeks old. Draw a blood sample from each cat and test individually for antibodies against feline panleucopenia virus and canine parvovirus to determine susceptibility. Vaccinate 5 cats by the recommended schedule. Carry out leucocyte counts 8 days and 4 days before challenge and calculate the mean of the 2 counts to serve as the initial value. 20 to 22 days after

the last vaccination, challenge each cat by the intraperitoneal injection of a suspension of pathogenic feline panleucopenia virus. Observe the cats for 14 days. Carry out leucocyte counts on the fourth, sixth, eighth and tenth days after challenge. The test is not valid unless the 5 control cats all show on not fewer than one occasion a diminution in the number of leucocytes of at least 75 per cent of the initial value; these animals may die from panleucopenia. The vaccine complies with the test if the 5 vaccinated cats remain in excellent health and show no sign of leucopenia; that is to say, the diminution in the number of leucocytes does not exceed, in any of the four counts, 50 per cent of the initial value.

BATCH TESTING

Batch potency test. For routine testing of batches of vaccine a test based on production of haemagglutination-inhibiting antibodies in guinea-pigs may be used instead of test A or B described under Potency if a satisfactory correlation with the test for immunogenicity has been established.

IDENTIFICATION

When injected into animals, the vaccine stimulates the production of antibodies against the parvovirus present in the vaccine.

TESTS

Safety. Use cats of the minimum age recommended for vaccination and preferably having no antibodies against feline panleucopenia virus or against canine parvovirus or, where justified, use cats with a low level of such antibodies as long as they have not been vaccinated against feline panleucopenia virus or against canine parvovirus, and administration of the vaccine does not cause an anamnestic response. Administer by a recommended route a double dose of vaccine to each of 2 cats. Observe the animals for 14 days. No abnormal local or systemic reaction occurs.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Carry out test A or test B.

- A. Use 4 cats, 8 to 12 weeks old. Draw a blood sample from each cat and test individually for antibodies against feline panleucopenia virus and canine parvovirus to determine susceptibility. Inject by a recommended route one dose of vaccine into each of 2 cats. After 21 days, draw a blood sample from each cat and separate the serum from each sample. Inactivate each serum by heating at 56 °C for 30 min. To 1 volume of each serum add 9 volumes of a 200 g/l suspension of *light kaolin R* in *phosphate buffered saline pH 7.4 R*. Shake each mixture for 20 min. Centrifuge, collect the supernatant liquid and mix with 1 volume of a concentrated suspension of pig erythrocytes. Allow to stand at 4 °C for 60 min and centrifuge. The dilution of the serum obtained is 1:10. Using each serum, prepare a series of twofold dilutions. To 0.025 ml of each of the latter dilutions add 0.025 ml of a suspension of canine parvovirus or feline panleucopenia virus antigen containing 4 haemagglutinating units. Allow to stand at 37 °C for 30 min and add 0.05 ml of a suspension of pig erythrocytes containing 30×10^6 cells per millilitre. Allow to stand at 4 °C for 90 min and note the last dilution of serum that still completely inhibits haemagglutination. The vaccine complies with the test if both vaccinated cats have developed titres of

at least 1:20. The test is not valid if either control cat develops antibodies against canine parvovirus or feline panleucopenia virus.

- B. Vaccinate according to the recommended schedule, 2 cats, 8 to 12 weeks old and having antibody titres less than 4 ND₅₀ (neutralising dose 50 per cent) per 0.1 ml of serum measured by the method described below. 14 days after vaccination, examine the serum of each animal as follows. Heat the serum at 56 °C for 30 min and prepare serial dilutions using a medium suitable for feline cells. Add to each dilution an equal volume of a virus suspension containing an amount of virus such that when the volume of serum-virus mixture appropriate for the assay system is inoculated into cell cultures, each culture receives approximately 10^4 CCID₅₀. Incubate the mixtures at 37 °C for 1 h and inoculate four feline cell cultures with a suitable volume of each mixture. Incubate the cell cultures at 37 °C for 7 days, passage and incubate for a further 7 days. Examine the cultures for evidence of specific cytopathic effects and calculate the antibody titre. The vaccine complies with the test if the mean titre is not less than 32 ND₅₀ per 0.1 ml of serum. If one cat fails to respond, repeat the test using 2 more cats and calculate the result as the mean of the titres obtained from all of the 3 cats that have responded.

01/2005:0251

FELINE INFECTIOUS ENTERITIS (FELINE PANLEUCOPENIA) VACCINE (LIVE)

Vaccinum panleucopeniae felinae infectivae vivum

DEFINITION

Feline infectious enteritis (feline panleucopenia) vaccine (live) is a preparation of a suitable strain of feline panleucopenia virus.

PRODUCTION

The virus is propagated in suitable cell cultures (5.2.4). The virus suspension is harvested and may be purified and concentrated. It is mixed with a suitable stabilising solution. The vaccine may be freeze-dried.

CHOICE OF VACCINE STRAIN

The vaccine strain shall have been shown to be satisfactory with respect to safety (including safety for pregnant queens if such use is not contra-indicated or if the virus is excreted in the faeces), absence of increase in virulence and immunogenicity.

The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Safety. *Each test is carried out for each recommended route of administration.* Use 5 cats, of the minimum age recommended for vaccination and free from specific haemagglutination-inhibiting antibodies against feline panleucopenia virus and canine parvovirus. Make counts of leucocytes in circulating blood on days 8 and 4 before injection of the vaccine strain and calculate the mean of the 2 counts to serve as the initial value. Administer to each cat by a recommended route a quantity of virus corresponding to at least 10 times the maximum virus titre that may be expected in a batch of vaccine and at the lowest level of attenuation. Observe the animals for 21 days. Make leucocyte counts on the fourth, sixth, eighth and tenth days after inoculation. The strain complies with the test if: the

cats remain in good health and there is no abnormal local or systemic reaction; for each animal and for each blood count, the number of leucocytes is not less than 50 per cent of the initial value.

Increase in virulence. Use 2 cats of the minimum age recommended for vaccination and which do not have haemagglutination-inhibiting antibodies against feline panleucopenia virus and canine parvovirus. Administer to each cat, by a recommended route, a quantity of virus suitable to allow maximum recovery of the virus for subsequent passages. From the second to the tenth day after administration of the virus, collect the faeces from each cat and check for the presence of the virus; pool faeces containing virus. Administer 1 ml of the suspension of pooled faeces by the oronasal route to each of 2 other cats of the same age and susceptibility; repeat this operation a further 4 times. Verify the presence of virus at each passage. If the virus is not found, carry out a second series of passages; if the virus is not found in one of the second series of passages, the vaccine strain complies with the test. The vaccine strain complies with the test if: no cat dies or shows signs attributable to the vaccine; no indication of increase of virulence compared to the original vaccinal virus is observed; account is taken, notably, of the count of white blood cells, of results of histological examination of the thymus and of the titre of excreted virus.

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity of the strain.

BATCH TESTING

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot, subject to agreement by the competent authority.

IDENTIFICATION

Carry out replication of the vaccine virus in a susceptible cell line in a substrate suitable for a fluorescent antibody test or peroxidase test. Prepare suitable controls. Test a proportion of the cells with monoclonal antibodies specific for feline panleucopenia virus and a proportion with monoclonal antibodies specific for canine parvovirus. Feline panleucopenia virus is detected but no canine parvovirus is detected in the cells inoculated with the vaccine.

TESTS

Safety. Use 2 cats of the minimum age recommended for vaccination and having no antibodies against feline panleucopenia virus or against canine parvovirus. Administer 10 doses of the vaccine to each cat, by a recommended route. Observe the animals for 14 days. No abnormal local or systemic reaction occurs.

Extraneous viruses. Neutralise the vaccine using a suitable monospecific antiserum against feline panleucopenia virus and inoculate into suitable cell cultures; make at least one passage and maintain the cultures for 14 days. Examine the cultures for cytopathic effects and carry out tests for haemadsorbing agents. No signs of viral contamination occur in the cell cultures.

Bacterial and fungal contamination. The vaccine, reconstituted if necessary, complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

Mycoplasmas (2.6.7). The vaccine complies with the test for mycoplasmas.

Virus titre. Reconstitute the vaccine, if necessary, and titrate in suitable cell cultures. One dose of vaccine contains not less than the quantity of virus equivalent to the minimum titre stated on the label.

POTENCY

Use 10 susceptible cats, 8 to 12 weeks old. Draw a blood sample from each cat and test individually for antibodies against feline panleucopenia virus and canine parvovirus to determine susceptibility. Vaccinate 5 cats by the recommended schedule. Carry out leucocyte counts 8 days and 4 days before challenge and calculate the mean of the 2 counts to serve as the initial value. 20 to 22 days after the last vaccination, challenge each cat by the intraperitoneal injection of a suspension of pathogenic feline panleucopenia virus. Observe the cats for 14 days. Carry out leucocyte counts on the fourth, sixth, eighth and tenth days after challenge. The test is not valid unless the 5 control cats all show on not fewer than one occasion a diminution in the number of leucocytes of at least 75 per cent of the initial value; these animals may die from panleucopenia. The vaccine complies with the test if the 5 vaccinated cats remain in excellent health and show no sign of leucopenia; that is to say, the diminution in the number of leucocytes does not exceed, in any of the four counts, 50 per cent of the initial value.

LABELLING

The label states that the vaccine should not be used in pregnant queens (unless it has been shown to be safe in such conditions).

01/2005:1321

FELINE LEUKAEMIA VACCINE (INACTIVATED)

Vaccinum leucosis felinae inactivatum

DEFINITION

Feline leukaemia vaccine (inactivated) is a preparation of immunogens from a suitable strain of feline leukaemia virus.

PRODUCTION

The immunogens consist either of a suitable strain of feline leukaemia virus inactivated in such a manner that adequate immunogenicity is maintained or of a fraction of the virus with adequate immunogenic properties; the immunogenic fraction may be produced by recombinant DNA technology. Where applicable, the test for inactivation is carried out using a quantity of inactivated virus equivalent to not less than 25 doses of vaccine and two passages in the same type of cell cultures as used for the production of the vaccine or in cell cultures shown to be at least as sensitive; no live virus is detected.

The vaccine may contain an adjuvant.

CHOICE OF VACCINE COMPOSITION

The choice of the feline leukaemia virus strains and/or of the antigens included in the vaccine composition is made in such a manner as to ensure the safety (5.2.6) (including safety for pregnant queens if the vaccine may be used in such animals) and immunogenicity (5.2.7) of the vaccine. The following tests may be used during demonstration of safety and immunogenicity.

Safety. Carry out the test for each intended route of administration. Use animals that do not have antibodies against gp 70 antigen of feline leukaemia virus nor display

viraemia or antigenaemia at the time of the test; absence of antibodies and antigen is demonstrated by enzyme-linked immunosorbent assay (2.7.1).

- A. Vaccinate, according to the intended schedule, not fewer than ten cats of the minimum age recommended for vaccination. Keep five cats as controls. Record the rectal temperature of each cat on the day before each vaccination, at the time of vaccination, 4 h and 8 h later, and once per day during the four following days. Observe the animals for at least 4 weeks after the last vaccination. No abnormal local or systemic reaction occurs during the test. 1, 2 and 4 weeks after the last vaccination, submit the animals to suitable tests for evidence of an immunosuppressive effect. The vaccine complies with the test if no significant difference is observed in vaccinated animals compared with controls.
- B. Inject two doses of vaccine by one of the intended routes to not fewer than ten cats of the minimum age recommended for vaccination. At the end of the period of time stated in the instructions for use, inject one dose of vaccine to each animal. Where the instructions for use recommend it, administer a third injection after the period indicated. Observe the animals for 14 days after the last administration. The vaccine complies with the test if no abnormal local or systemic reaction occurs during the test.
- C. If the vaccine is not contra-indicated for use in pregnant queens, inject two doses of vaccine into each of not fewer than ten cats at different stages of pregnancy. Observe the cats until parturition and note any effects on gestation and the offspring. The vaccine complies with the test if no abnormal local or systemic reaction occurs during the test.

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity of the vaccine.

IN-PROCESS CONTROL TESTS

During production, suitable immunochemical tests are carried out for the evaluation of the quality and purity of the viral antigens included in the vaccine composition. The values found are within the limits approved for the particular vaccine.

BATCH TESTING

Potency. The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated alternative method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

Bacterial endotoxins. For vaccines produced by recombinant DNA technology with a bacterial host cell such as *Escherichia coli*, a test for bacterial endotoxins (2.6.14) is carried out on each final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the antigen immediately before addition of the adjuvant. The value found is within the limit approved for the particular vaccine and which has been shown to be safe for cats.

IDENTIFICATION

When injected into healthy, seronegative cats, the vaccine stimulates the production of specific antibodies against the antigen or antigens stated on the label.

TESTS

Safety. Use two cats of the minimum age recommended for vaccination and that do not have antibodies against feline leukaemia virus. Inject by a recommended route a double dose of vaccine into each animal. Observe the animals for 14 days. The vaccine complies with the test if no abnormal local or systemic reaction is produced.

Inactivation. If the vaccine contains inactivated virus, carry out a test for residual live feline leukaemia virus by making two passages on susceptible cell cultures. No virus is detected. If the vaccine contains an adjuvant, if possible separate the adjuvant from the liquid phase by a method that does not inactivate the virus nor interfere in any other way with the detection of virus.

Sterility. The vaccine complies with the test for sterility prescribed in *Vaccines for veterinary use* (0062).

POTENCY

Use not fewer than twenty-five susceptible cats of the minimum age recommended for vaccination, free from antibodies against the antigens of feline leukaemia virus and against the feline oncogene membrane antigen (anti-FOCMA antibodies), and showing no viraemia or antigenaemia at the time of the test. Vaccinate not fewer than fifteen cats by a recommended route in accordance with the instructions for use. Keep not fewer than ten cats as controls. Observe the animals for at least 14 days after the last administration of vaccine. Inject by the peritoneal or oronasal route, on one or several occasions, a quantity of a virulent strain of feline leukaemia virus sufficient to induce persistent viraemia or antigenaemia in not fewer than 80 per cent of susceptible animals; use for the challenge an epidemiologically relevant strain consisting predominantly of type A virus. Observe the animals for 15 weeks and, from the third week onwards, test each week for viraemia or antigenaemia (p27 protein) by suitable methods such as immunofluorescence on circulating leucocytes or enzyme-linked immunosorbent assay. A cat is considered persistently infected if it shows positive viraemia or antigenaemia for three consecutive weeks or on five occasions, consecutively or not, between the third and the fifteenth week. The test is not valid if fewer than 80 per cent of the control cats are persistently infected. The vaccine complies with the test if not fewer than 80 per cent of the vaccinated cats show no persistent infection.

LABELLING

The label states the antigen or antigens contained in the vaccine.

01/2005:1207

FELINE VIRAL RHINOTRACHEITIS VACCINE (INACTIVATED)

*Vaccinum rhinotracheitidis viralis felinae
inactivatum*

DEFINITION

Feline viral rhinotracheitis vaccine (inactivated) is a preparation of a suitable strain of feline rhinotracheitis virus (feline herpesvirus 1) that has been inactivated while maintaining adequate immunogenic properties or of an inactivated fraction of the virus having adequate immunogenic properties.

PRODUCTION

The vaccine strain is grown in suitable cell cultures (5.2.4). The viral suspension is harvested and inactivated.

The test for inactivation is carried out using 2 passages in cell cultures of the same type as those used for preparation of the vaccine or in cell cultures shown to be at least as sensitive; the quantity of virus used in the test is equivalent to not less than 25 doses of vaccine. No live virus is detected.

The virus may be fragmented and the fragments may be purified and concentrated. The vaccine may be adjuvanted; it may be freeze-dried.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety and immunogenicity in cats. The following test may be used during demonstration of efficacy (5.2.7).

Immunogenicity. The test described under Potency, carried out using vaccine prepared from the most attenuated virus that will be attained during production, is suitable to demonstrate immunogenicity of the strain.

BATCH TESTING

The test described under Potency is not necessarily carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable alternative validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Batch potency test. Use a group of 15 seronegative mice. Administer half a dose of the vaccine to each mouse and 7 days later repeat the administration. 21 days after the first injection, take blood samples and determine the level of antibodies against feline rhinotracheitis virus by a suitable immunochemical method (2.7.1), such as an immunofluorescence technique using pools of serum from groups of 3 mice. The antibody levels are not significantly lower than those obtained with a batch of vaccine that has given satisfactory results in the test described under Potency.

IDENTIFICATION

When administered to susceptible animals, the vaccine stimulates the production of specific serum antibodies against feline rhinotracheitis virus or against the fraction of the virus used to produce the vaccine.

TESTS

Safety. Use cats 8 to 12 weeks old and preferably having no feline rhinotracheitis virus antibodies or antibodies to a fraction of the virus, or, where justified, use cats with a low level of such antibodies as long as they have not been vaccinated against viral rhinotracheitis and administration of the vaccine does not cause an anamnestic response. Administer a double dose of vaccine by a recommended route to each of 2 cats. Observe the cats for 14 days. No abnormal local or systemic reaction occurs.

Inactivation. Carry out a test for residual infectious feline rhinotracheitis virus using 10 doses of vaccine and 2 passages in cell cultures of the same type as those used for preparation of the vaccine or in other suitably sensitive cell cultures. No live virus is detected. If the vaccine contains an adjuvant that interferes with the test, where possible separate the adjuvant from the liquid phase by a method that does not inactivate or otherwise interfere with detection of live virus.

Sterility. The reconstituted vaccine complies with the test for sterility prescribed under *Vaccines for veterinary use* (0062).

POTENCY

Use cats 8 to 12 weeks old and which do not have antibodies against feline rhinotracheitis virus or against a fraction of the virus. Vaccinate 10 cats according to the instructions for use and keep 10 cats as controls. 4 weeks after the last administration of vaccine, administer intranasally to each of the 20 cats, a quantity of virulent feline rhinotracheitis virus sufficient to produce in susceptible cats typical signs of disease such as fever, nasal discharge and cough. Observe the cats for 14 days; collect nasal washings daily on days 2 to 14 after challenge to test for virus excretion. Note daily the body temperature and signs of disease using the scoring system shown below. If any sign of disease is observed on more than one day, record the score once only. The vaccine complies with the test if the score for the vaccinated cats is significantly lower than that for the controls.

Sign	Score

FELINE VIRAL RHINOTRACHEITIS VACCINE (LIVE), FREEZE-DRIED

Vaccinum rhinotracheitidis viralis felinae vivum cryodesiccatum

DEFINITION

Freeze-dried feline viral rhinotracheitis vaccine (live) is a preparation of a suitable strain of feline rhinotracheitis virus (feline herpesvirus 1).

PRODUCTION

The vaccine strain is grown in suitable cell cultures (5.2.4). The viral suspension is harvested and mixed with a suitable stabilising solution. The mixture is subsequently freeze-dried.

CHOICE OF VACCINE STRAIN

Only a virus strain shown to be satisfactory with respect to safety, reversion to virulence and immunogenicity may be used in the preparation of the vaccine; if the vaccine is not contra-indicated in pregnant queens, the safety for such use is demonstrated. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Safety. Administer by a recommended route to each of ten cats, of the minimum age stated for vaccination and which do not have antibodies against feline rhinotracheitis virus, a quantity of virus equivalent to ten times the maximum titre that may be expected in a batch of vaccine. Observe the cats for 21 days. They remain in good health and show no abnormal local or systemic reaction.

Reversion to virulence. Administer by a recommended route to each of two cats that do not have antibodies against feline rhinotracheitis virus, a quantity of virus that will allow optimal re-isolation of the virus for subsequent passages (for example ten times the minimum titre to be stated on the label). Kill the cats 2 to 4 days after the inoculation and remove the nasal mucus, tonsils and local lymphatic ganglia and the trachea; mix the samples, homogenise in 10 ml of buffered saline and allow to settle; inoculate 1 ml of supernatant intranasally into two cats; repeat this operation not fewer than five times; verify the presence of virus at each passage; if the virus is not recovered, carry out a second series of passages. Observe the cats given the last passage for 21 days and compare any reactions with those seen in the safety test described above. No evidence of an increase in virulence is seen compared to the original virus.

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity of the strain.

BATCH TESTING

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot, subject to agreement by the competent authority.

IDENTIFICATION

When mixed with a monospecific antiserum, the reconstituted vaccine no longer infects susceptible cell cultures into which it is inoculated.

TESTS

Safety. Administer ten doses of the vaccine in a suitable volume by a recommended route to two cats, 8 to 12 weeks old, that do not have antibodies against feline rhinotracheitis virus. Observe the cats for 14 days. They remain in good health and show no abnormal local or systemic reaction.

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

Mycoplasmas (2.6.7). The reconstituted vaccine complies with the test for mycoplasmas.

Extraneous viruses. Neutralise the vaccinal virus using a monospecific antiserum and inoculate into suitable cell cultures; make at least one passage and maintain the cultures for 14 days. No cytopathic effect develops; the cells show no evidence of the presence of haemadsorbing agents or other signs of viral contamination.

Virus titre. Titrate the reconstituted vaccine in susceptible cell cultures at a temperature favourable to replication of the virus. One dose of vaccine contains not less than the quantity of virus corresponding to the minimum virus titre stated on the label.

POTENCY

Use cats 8 to 12 weeks old and which do not have antibodies against feline viral rhinotracheitis virus. Vaccinate ten cats according to the instructions for use and keep ten cats as controls. Four weeks after the last administration of vaccine, administer intranasally to each cat a quantity of virulent feline rhinotracheitis virus sufficient to produce in susceptible cats typical signs of disease such as fever, nasal discharge and cough. Observe the cats for 14 days; collect nasal washings daily on days 2 to 14 after challenge to test for virus excretion. Note daily the body temperature and signs of disease using the scoring system shown below. If any sign of disease is observed on more than one day, record the score once only. The vaccine complies with the test if the score for the vaccinated cats is significantly lower than that for the controls.

FOOT-AND-MOUTH DISEASE (RUMINANTS) VACCINE (INACTIVATED)

*Vaccinum aphtharum epizooticarum
inactivatum ad ruminantes*

DEFINITION

Foot-and-mouth disease (ruminants) vaccine (inactivated) is a liquid preparation containing one or more types or sub-types of foot-and-mouth disease virus inactivated without impairing their immunogenic activity.

PRODUCTION

The virus is grown either in suspensions of cattle-tongue epithelium obtained immediately after slaughter of healthy animals, or, preferably, in suitable cell cultures (5.2.4). The

virus is separated from cellular material by filtration or other suitable procedures and the virus is inactivated in suitable conditions.

The vaccine is prepared from inactivated antigen by blending with one or more adjuvants. The antigen may be concentrated and purified by a number of procedures. The concentrated antigen is used for the preparation of vaccine immediately or after storage at a temperature not exceeding -90°C , unless stability of the antigen at a higher temperature has been demonstrated.

Validation of the inactivation procedure. During inactivation, the virus titre is monitored by a sensitive and reproducible technique. The inactivation procedure is not satisfactory unless the decrease in virus titre, plotted logarithmically, is linear and extrapolation indicates that there is less than 1 infectious virus unit per 10^4 litres of liquid preparation at the end of inactivation.

BULK INACTIVATED ANTIGEN

Inactivation. A proportion of each batch of bulk inactivated antigen representing at least 200 doses is tested for freedom from infectious virus by inoculation into sensitive cell cultures. For this purpose, the sample of the inactivated antigen is concentrated to allow testing of such large samples in cell cultures. It must be shown that the selected concentration and assay systems are not detrimental to detection of infectious virus within the test sample and that the concentrated inactivated antigen does not interfere with virus replication or cause toxic changes.

Antigenicity. The antigen content of each batch of bulk inactivated antigen is determined by an *in vitro* method (for example, 146S-particle measurement by sucrose density gradient centrifugation and ultraviolet spectrophotometry at 259 nm).

Safety. A representative sample of the bulk inactivated antigen may be diluted and blended with the adjuvants for safety testing in cattle, as described below.

Sterility. The bulk inactivated antigen, the adjuvants and all dilution buffers comply with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

Potency. A representative sample of the bulk inactivated antigen may be diluted and blended with the adjuvants for potency testing in cattle, as described below.

In situations of extreme urgency and subject to agreement by the competent authority, a batch of vaccine may be released before completion of the tests and the determination of potency if a test for sterility has been carried out on the bulk inactivated antigen and all other components of the vaccine and if the test for safety and the determination of potency have been carried out on a representative batch of vaccine prepared from the same bulk inactivated antigen. In this context, a batch is not considered to be representative unless it has been prepared using the same amount of antigen and with the same formulation as the batch to be released.

IDENTIFICATION

The serum of a susceptible animal that has been immunised with the vaccine neutralises the types or sub-types of the virus used to prepare the vaccine, when tested by a suitably sensitive method.

TESTS

Safety. Use three non-vaccinated cattle not less than 6 months old having serum free from foot-and-mouth disease antibodies and coming from regions free from foot-and-mouth disease. Inoculate each animal intradermally into the tongue at not fewer than twenty points, using 0.1 ml of the vaccine at each point. Observe the animals for not less than 4 days. No lesions or signs of foot-and-mouth disease occur. At the end of the observation period, inject into the same animals by the prescribed route three times the dose stated on the label. Observe the animals for 6 days after this inoculation. No lesions or clinical signs of foot-and-mouth disease occur on the feet or tongue and any reaction at the site of injection remains insignificant.

Sterility. It complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

POTENCY

The potency of the vaccine is expressed as the number of 50 per cent cattle protective doses (PD_{50}) contained in the dose stated on the label. The PD_{50} is determined in animals given primary vaccination and challenged by the inoculation of 10 000 ID_{50} of virulent bovine virus of the same type or sub-type as that used in the preparation of the vaccine in the conditions described below.

The vaccine contains at least 3 PD_{50} per dose for cattle.

Carry out a potency test for each type and sub-type of foot-and-mouth disease virus present in the vaccine.

Use cattle not less than 6 months old, obtained from areas free from foot-and-mouth disease, which have never been vaccinated against foot-and-mouth disease and are free from antibodies neutralising the different types of foot-and-mouth disease virus. Vaccinate not fewer than three groups of not fewer than five cattle per group by the route stated on the label. Use a different dose of the vaccine for each group. Administer the different doses by injecting different volumes of the vaccine rather than by dilution of the vaccine. For example, if the label states that the injection of 2 ml corresponds to the administration of 1 dose of vaccine, a 1/4 dose of vaccine would be obtained by injecting 0.5 ml, and a 1/10 dose would be obtained by injecting 0.2 ml. Three weeks after the vaccination, challenge the vaccinated animals and a control group of two animals with a suspension of virus that has been obtained from cattle and that is fully virulent and of the same type or sub-type as that used in the preparation of the vaccine, by inoculating a total of 10 000 ID_{50} intradermally into two sites on the upper surface of the tongue (0.1 ml per site). Observe the animals for 8 days and then slaughter. Unprotected animals show lesions at sites other than the tongue. Protected animals may display lingual lesions. The test is not valid unless each control animal shows lesions on at least three feet. From the number of protected animals in each group, calculate the PD_{50} content of the vaccine.

STORAGE

The vaccine must not be frozen.

LABELLING

The label states:

- the method of preparation,
- the types and sub-types of virus used to prepare the vaccine.

01/2005:0649

FOWL-POX VACCINE (LIVE)

Vaccinum variolae gallinae vivum

1. DEFINITION

Fowl-pox vaccine (live) is a preparation of a suitable strain of avian pox virus. This monograph applies to vaccines intended for administration to chickens for active immunisation.

2. PRODUCTION

2-1. PREPARATION OF THE VACCINE

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. SUBSTRATE FOR VIRUS PROPAGATION

2-2-1. Embryonated hens' eggs. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (5.2.2).

2-2-2. Cell cultures. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (5.2.4).

2-3. SEED LOTS

2-3-1. Extraneous agents. The master seed lot complies with the tests for extraneous agents in seed lots (2.6.24). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. CHOICE OF VACCINE VIRUS

The vaccine virus shall be shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during demonstration of safety and immunogenicity.

2-4-1. Safety. Carry out the test for each route and method of administration to be recommended for vaccination using in each case chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test use not fewer than 20 chickens, from an SPF flock (5.2.2). Administer to each chicken a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in a dose of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 10 per cent of the chickens die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no chicken shows notable clinical signs of fowl pox or dies from causes attributable to the vaccine virus.

2-4-2. Increase in virulence. Administer by a suitable route a quantity of the vaccine virus that will allow recovery of virus for the passages described below to each of 5 chickens not older than the minimum age to be recommended for vaccination and from an SPF flock (5.2.2). Use the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. Prepare 4 to 7 days after administration a suspension from the induced skin lesions of each chicken and pool these samples. Administer 0.2 ml of the pooled samples by cutaneous scarification of the comb or other unfeathered part of the body, or by another suitable method to each of 5 other chickens not older than the minimum age

to be recommended for vaccination and from an SPF flock (5.2.2). Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. Care must be taken to avoid contamination by virus from previous passages. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for safety (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged virus that has been recovered. Administer the virus by the route recommended for vaccination likely to be the least safe. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. Immunogenicity. A test is carried out for each route and method of administration to be recommended using in each case chickens not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each chicken is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. Use for the test not fewer than 30 chickens of the same origin and from an SPF flock (5.2.2). Vaccinate by a recommended route not fewer than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 21 days by the feather-follicle route with a sufficient quantity of virulent fowl-pox virus. Observe the chickens at least daily for 21 days after challenge. Record the deaths and the number of surviving chickens that show clinical signs of disease. Examine each surviving chicken for macroscopic lesions: cutaneous lesions of the comb, wattle and other unfeathered areas of the skin and diphtherical lesions of the mucous membranes of the oro-pharyngeal area.

The test is not valid if:

- during the observation period after challenge fewer than 90 per cent of the control chickens die or show severe clinical signs of fowl pox, including notable macroscopical lesions of the skin or mucous membranes of the oro-pharyngeal area,
- and/or during the period between vaccination and challenge, more than 10 per cent of the control or vaccinated chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not less than 90 per cent of the vaccinated chickens survive and show no notable clinical signs of disease, including macroscopical lesions of the skin and mucous membranes of the oro-pharyngeal area.

3. BATCH TESTS

3-1. Identification. Carry out an immunostaining test in cell cultures to demonstrate the presence of the vaccine virus. For egg adapted strains, inoculate the vaccine into eggs and notice the characteristic lesions.

3-2. Bacteria and fungi

Vaccines intended for administration by injection, scarification or piercing of the wing web comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062).

Vaccines not intended for administration by injection, scarification or piercing of the wing web either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062) or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for

microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use* (0062).

3-3. Mycoplasmas. The vaccine complies with the test for mycoplasmas (2.6.7).

3-4. Extraneous agents. The vaccine complies with the tests for extraneous agents in batches of finished product (2.6.25).

3-5. Safety. Use not fewer than 10 chickens from an SPF flock (5.2.2) of the youngest age recommended for vaccination. For vaccines recommended for use in chickens older than 6 weeks, chickens 6 weeks old may be used. Administer 10 doses of the vaccine to each chicken by a recommended route. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. Virus titre. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (5.2.2) or into suitable cell cultures (5.2.4). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. Potency. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-4-3) when administered according to the recommended schedule by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2005:1521

FURUNCULOSIS VACCINE (INACTIVATED, OIL-ADJUVANTED, INJECTABLE) FOR SALMONIDS

*Vaccinum furunculosis ad salmonidas
inactivatum cum adjuvatione oleosa
ad iniectionem*

DEFINITION

Furunculosis vaccine (inactivated, oil-adjuvanted, injectable) for salmonids is prepared from cultures of one or more suitable strains of *Aeromonas salmonicida* subsp. *salmonicida*.

PRODUCTION

The strains of *A. salmonicida* are cultured and harvested separately. The harvests are inactivated by a suitable method. They may be purified and concentrated. Whole or disrupted cells may be used and the vaccine may contain extracellular products of the bacterium released into the growth medium. The vaccine contains an oily adjuvant.

CHOICE OF VACCINE COMPOSITION

The strains included in the vaccine are shown to be suitable with respect to production of antigens of assumed immunological importance. The vaccine is shown to be

satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) in the species of fish for which it is intended. The following tests may be used during demonstration of safety and immunogenicity.

Safety

A. During development of the vaccine, safety is tested on 3 different batches. A test is carried out in each species of fish for which the vaccine is intended. The fish used are from a population that does not have specific antibodies against *A. salmonicida* subsp. *salmonicida* and has not been vaccinated against or exposed to furunculosis. The test is carried out in the conditions recommended for the use of the vaccine with a water temperature not less than 10 °C. An amount of vaccine corresponding to twice the recommended dose per mass unit is administered intraperitoneally into each of not fewer than 50 fish of the minimum body mass recommended for vaccination. The fish are observed for 21 days. No abnormal local or systemic reaction occurs. The test is invalid if more than 6 per cent of the fish die from causes not attributable to the vaccine.

B. Safety is also demonstrated in field trials by administering the intended dose to a sufficient number of fish in not fewer than 2 sets of premises. Samples of 30 fish are taken on 3 occasions (after vaccination, at the middle of the rearing period and at slaughter) and examined for local reactions in the body cavity. Moderate lesions involving localised adhesions between viscera or between viscera and the abdominal wall and slight opaqueness and/or sparse pigmentation of the peritoneum are acceptable. Extensive lesions including adhesions between greater parts of the abdominal organs, massive pigmentation and/or obvious thickening and opaqueness of greater areas of the peritoneum are unacceptable if they occur in more than 10 per cent of the fish in any sample. Such lesions include adhesions that give the viscera a "one-unit" appearance and/or lead to manifest laceration of the peritoneum following evisceration.

Immunogenicity. The test described under Potency is suitable to demonstrate the immunogenicity of the vaccine.

BATCH TESTING

Batch potency test. For routine testing of batches of vaccine, the test described under Potency may be carried out using not fewer than 30 fish per group; alternatively, a suitable validated test based on antibody response may be carried out, the criteria being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Use fish from a population that does not have specific antibodies against *A. salmonicida* subsp. *salmonicida* and that are within defined limits for body mass. Carry out the test at a defined temperature. Inject intraperitoneally into each of not fewer than 25 fish one dose of vaccine, according to the instructions for use. Perform mock vaccination on a control group of not fewer than 10 fish. Collect blood samples at a defined time after vaccination. Determine for each sample the level of specific antibodies against *A. salmonicida* subsp. *salmonicida* by a suitable immunochemical method (2.7.1). The vaccine complies with the test if the mean level of antibodies is not significantly lower than that found for a batch that gave satisfactory results in the test described under Potency. The test is not valid if the control group shows antibodies against *A. salmonicida* subsp. *salmonicida*.

IDENTIFICATION

01/2005:0696

When injected into fish that do not have specific antibodies against *A. salmonicida*, the vaccine stimulates the production of such antibodies.

TESTS

Safety. Use not fewer than 10 fish of one of the species for which the vaccine is intended, having, where possible, the minimum body mass recommended for vaccination; if fish of the minimum body mass are not available, use fish not greater than twice this mass. Use fish from a population that preferably does not have specific antibodies against *A. salmonicida* subsp. *salmonicida* or, where justified, use fish from a population with a low level of such antibodies as long as they have not been vaccinated against or exposed to furunculosis and administration of the vaccine does not cause an anamnestic response. Carry out the test in the conditions recommended for use of the vaccine with a water temperature not less than 10 °C. Administer intraperitoneally to each fish an amount of vaccine corresponding to twice the recommended dose per mass unit. Observe the animals for 21 days. No abnormal local or systemic reaction attributable to the vaccine occurs. The test is invalid if more than 10 per cent of the fish die from causes not attributable to the vaccine.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Carry out the test according to a protocol defining limits of body mass for the fish, water source, water flow and temperature limits, and preparation of a standardised challenge. Vaccinate not fewer than 100 fish by a recommended route, according to the instructions for use. Perform mock vaccination on a control group of not fewer than 100 fish; mark vaccinated and control fish for identification. Keep all the fish in the same tank or mix equal numbers of controls and vaccinates in each tank if more than one tank is used. Carry out challenge by injection at a fixed time interval after vaccination, defined according to the statement regarding development of immunity. Use for challenge a culture of *A. salmonicida* subsp. *salmonicida* whose virulence has been verified. Observe the fish daily until at least 60 per cent specific mortality is reached in the control group. Plot for both vaccinates and controls a curve of specific mortality against time from challenge and determine by interpolation the time corresponding to 60 per cent specific mortality in controls. The test is invalid if the specific mortality is less than 60 per cent in the control group 21 days after the first death in the fish. Read from the curve for vaccinates the mortality (*M*) at the time corresponding to 60 per cent mortality in controls. Calculate the relative percentage survival (RPS) from the expression:

$$\left(1 - \frac{M}{60}\right) \times 100$$

The vaccine complies with the test if the RPS is not less than 80 per cent.

LABELLING

The label states information on the time needed for development of immunity after vaccination under the range of conditions corresponding to the recommended use.

INFECTIOUS BOVINE RHINOTRACHEITIS VACCINE (LIVE), FREEZE-DRIED

*Vaccinum rhinotracheitidis infectivae
bovinae vivum cryodesiccatum*

DEFINITION

Freeze-dried infectious bovine rhinotracheitis vaccine (live) is a preparation of one or more attenuated strains of infectious bovine rhinotracheitis virus (bovine herpesvirus 1).

PRODUCTION

The virus is grown in suitable cell cultures (5.2.4). The viral suspension is collected and mixed with a suitable stabilising solution. The mixture is subsequently freeze-dried.

CHOICE OF VACCINE STRAIN

Only a virus strain shown to be satisfactory with respect to the following characteristics may be used in the preparation of the vaccine: safety (including absence of abortigenicity and passage through the placenta); reversion to virulence and immunogenicity. The strain may have markers. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Safety. Use 5 calves 3 months old, or of the minimum age to be recommended for vaccination if this is less than 3 months, and that do not have antibodies against infectious bovine rhinotracheitis virus. Administer to each calf, by the intended route, a quantity of virus corresponding to 10 doses of vaccine. The calves are observed for 21 days. No abnormal local or systemic reaction occurs.

Abortigenicity and passage through the placenta.

24 pregnant cows that do not have antibodies against infectious bovine rhinotracheitis virus are used for the test: 8 of the cows are in the fourth month of pregnancy, 8 in the fifth month and 8 in the sixth or seventh month. A quantity of virus equivalent to ten doses of vaccine is administered by the intended route to each cow. The cows are observed until the end of pregnancy. If abortion occurs, tests for infectious bovine rhinotracheitis virus are carried out; neither the virus nor viral antigens are present in the foetus or placenta. A test for antibodies against infectious bovine rhinotracheitis virus is carried out on calves born at term before ingestion of colostrum; no such antibodies are found.

Reversion to virulence. Suitable samples are taken from the 5 calves used for the test for safety at a time when the vaccinal virus can be easily detected. The presence and titre of virus in the samples are verified. The samples are then mixed and administered intranasally to 2 other calves of the same age having no antibodies against bovine rhinotracheitis virus. 5 further serial passages are carried out. The presence of the virus is verified at each passage. No abnormal local or systemic reaction occurs.

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity.

BATCH TESTING

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot, subject to agreement by the competent authority.

IDENTIFICATION

- A. Reconstitute the vaccine as stated on the label. When mixed with a suitable quantity of a monospecific antiserum, the reconstituted vaccine is no longer able to infect susceptible cell cultures into which it is inoculated.
- B. Any markers of the strain are verified.

TESTS

Safety. Use 2 calves 3 months old or of the minimum age recommended for vaccination if this is less than 3 months, having no antibodies against bovine rhinotracheitis virus. Administer 10 doses of the reconstituted vaccine to each calf by a recommended route. Observe the calves for 21 days. No abnormal local or systemic reaction occurs.

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

Mycoplasmas (2.6.7). The reconstituted vaccine complies with the test for mycoplasmas.

Extraneous viruses. Neutralise the vaccine using a monospecific antiserum and inoculate into suitable cell cultures. Maintain the cultures for 14 days and make a passage at 7 days. The cell cultures show no signs of viral contamination.

Virus titre. Titrate the reconstituted vaccine in susceptible cell cultures at a temperature favourable to replication of the virus. One dose of the vaccine contains not less than the quantity of virus equivalent to the minimum virus titre stated on the label.

POTENCY

Use susceptible calves, 2 to 3 months old and free from antibodies neutralising infectious bovine rhinotracheitis virus. Administer to five calves, by the route stated on the label a volume of the reconstituted vaccine containing a quantity of virus equivalent to the minimum virus titre stated on the label. Keep 2 calves as controls. After 21 days, administer intranasally to the seven calves a quantity of infectious bovine rhinotracheitis virus sufficient to produce typical signs of disease such as fever, ocular and nasal discharge and ulceration of the nasal mucosa in a susceptible calf. Observe the animals for 21 days. The vaccinated calves show no more than mild signs; the controls show typical signs. In not fewer than 4 of the 5 vaccinated calves, the maximum virus titre found in the nasal mucus is at least 100 times lower than the average of the maximum titres found in the control calves; the average number of days on which virus is excreted is at least 3 days less in vaccinated calves than in the control calves.

01/2005:2038

INFECTIOUS CHICKEN ANAEMIA VACCINE (LIVE)

Vaccinum anaemiae infectivae pulli vivum

1. DEFINITION

Infectious chicken anaemia vaccine (live) is a preparation of a suitable strain of chicken anaemia virus. This monograph applies to vaccines intended for administration to breeder chickens for active immunisation, to prevent excretion of the virus, to prevent or reduce egg transmission and to protect passively their future progeny.

2. PRODUCTION

2-1. PREPARATION OF THE VACCINE

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. SUBSTRATE FOR VIRUS PROPAGATION

2-2-1. Embryonated hens' eggs. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (5.2.2).

2-2-2. Cell cultures. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (5.2.4).

2-3. SEED LOTS

2-3-1. Extraneous agents. The master seed lot complies with the tests for extraneous agents in seed lots (2.6.24). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. CHOICE OF VACCINE VIRUS

The vaccine virus shall be shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during the demonstration of safety and immunogenicity.

2-4-1. Safety

2-4-1-1. General test. Carry out the test for each route and method of administration to be recommended for vaccination in chickens not older than the youngest age to be recommended for vaccination and from an SPF flock (5.2.2). Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test use not fewer than 20 chickens. Administer to each chicken a quantity of the vaccine virus not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. 14 days after vaccination, collect blood samples from half of the chickens and determine the haematocrit value. Kill these chickens and carry out post-mortem examination. Note any pathological changes attributable to chicken anaemia virus, such as thymic atrophy and specific bone-marrow lesions. Observe the remaining chickens at least daily for 21 days. The vaccine virus complies with the test if during the observation period no chicken shows notable clinical signs of chicken anaemia or dies from causes attributable to the vaccine virus.

2-4-1-2. Safety for young chicks. Use not fewer than twenty 1-day-old chicks from an SPF flock (5.2.2). Administer to each chick by the oculonasal route a quantity of the vaccine virus equivalent to not less than the maximum titre likely to be contained in 1 dose of the vaccine. Observe the chicks at least daily. Record the incidence of any clinical signs attributable to the vaccine virus, such as depression, and any deaths. 14 days after vaccination, collect blood samples from half of the chicks and determine the haematocrit value. Kill these chicks and carry out post-mortem examination. Note any pathological changes attributable to chicken anaemia virus, such as thymic atrophy and specific bone marrow lesions. Observe the remaining chicks at least daily for 21 days. Assess the extent to which the vaccine strain is pathogenic for 1-day-old susceptible chicks from the results of the clinical observations and mortality rates and the proportion of chicks examined at 14 days that show anaemia (haematocrit value less than 27 per cent) and signs of infectious chicken anaemia on post-mortem examination. The results are used to formulate the label statement on safety for young chicks.

2-4-2. Increase in virulence. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to a group of five 1-day-old chicks from an SPF flock (5.2.2), sequential passages, 5 times where possible, to further similar groups of 1-day-old chicks and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by the intramuscular route a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Prepare 7 to 9 days after administration a suspension from the liver of each chick and pool these samples. Depending on the tropism of the virus, other tissues such as spleen or bone marrow may be used. Administer 0.1 ml of the pooled samples by the intramuscular route to each of 5 other chicks of the same age and origin. Carry out this passage operation at least 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Carry out the tests for safety (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged vaccine virus that has been recovered. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. Immunogenicity. A test is carried out for each route and method of administration to be recommended using chickens from an SPF flock (5.2.2) not older than the youngest age to be recommended for vaccination. The test for prevention of virus excretion is intended to demonstrate absence of egg transmission. The quantity of the vaccine virus administered to each chicken is not greater than the minimum titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine.

2-4-3-1 Passive immunisation of chickens. Vaccinate according to the recommended schedule not fewer than 10 breeder chickens not older than the minimum age recommended for vaccination and from an SPF flock (5.2.2); keep not fewer than 10 unvaccinated breeder chickens of the same origin and from an SPF flock (5.2.2). At a suitable time after excretion of vaccine virus has ceased, collect fertilised eggs from each vaccinated and control breeder chicken and incubate them. Challenge at least 3 randomly chosen 1-day-old chickens from each vaccinated and control breeder chicken by intramuscular administration of a sufficient quantity of virulent chicken anaemia virus. Observe the chickens at least daily for 14 days after challenge. Record the deaths and the surviving chickens that show clinical signs of disease. At the end of the observation period determine the haematocrit value of each surviving chicken. Kill these chickens and carry out post-mortem examination. Note any pathological signs attributable to chicken anaemia virus, such as thymic atrophy and specific bone-marrow lesions. The test is not valid if:

- during the observation period after challenge fewer than 90 per cent of the chickens of the control breeder chickens die or show severe clinical signs of infectious

chicken anaemia, including haematocrit value under 27 per cent, and/or notable macroscopic lesions of the bone marrow and thymus,

- and/or during the period between vaccination and egg collection more than 10 per cent of vaccinated or control breeder chickens show notable clinical signs of disease or die from causes not attributable to the vaccine.

The vaccine complies with the test if during the observation period after challenge not fewer than 90 per cent of the chickens of the vaccinated breeder chickens survive and show no notable clinical signs of disease and/or macroscopic lesions of the bone marrow and thymus.

2-4-3-2. Prevention of virus excretion. Vaccinate according to the recommended schedule not fewer than 10 chickens not older than the minimum age recommended for vaccination and from an SPF flock (5.2.2). Maintain separately not fewer than 10 chickens of the same age and origin as controls. At a suitable time after excretion of vaccine virus has ceased, challenge all the chickens by intramuscular administration of a sufficient quantity of virulent chicken anaemia virus. Collect blood and faecal samples from the chickens on days 3, 5 and 7 after challenge and carry out a test for virus isolation to determine whether or not the chickens are viraemic and are excreting the virus. The test is not valid if:

- fewer than 70 per cent of the control chickens are viraemic and excrete the virus at one or more times of sampling,
- and/or during the period between vaccination and challenge more than 10 per cent of control or vaccinated chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine complies with the test if not fewer than 90 per cent of the vaccinated chickens do not develop viraemia or excrete the virus.

3 BATCH TESTING

3-1. Identification. The vaccine, diluted if necessary and mixed with a monospecific chicken anaemia virus antiserum, no longer infects susceptible cell cultures or eggs from an SPF flock (5.2.2) into which it is inoculated.

3-2. Bacteria and fungi. Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. Mycoplasmas. The vaccine complies with the test for mycoplasmas (2.6.7).

3-4. Extraneous agents. The vaccine complies with the tests for extraneous agents in batches of finished product (2.6.25).

3-5. Safety. Use not fewer than 10 chickens not older than the minimum age recommended for vaccination and from an SPF flock (5.2.2). Administer by a recommended route to each chicken 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The

vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. Virus titre. Titrate the vaccine virus by inoculation into suitable cell cultures (5.2.4) or eggs from an SPF flock (5.2.2). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. Potency. The vaccine complies with the requirements of the tests prescribed under Immunogenicity (sections 2-4-3-1 and 2-4-3-2) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

4. LABELLING

The label states to which extent the vaccine virus causes disease if it spreads to susceptible young chicks.

01/2005:1944

MANNHEIMIA VACCINE (INACTIVATED) FOR CATTLE

Vaccinum mannheimiae inactivatum ad bovidas

DEFINITION

Mannheimia vaccine (inactivated) for cattle is a preparation from cultures of one or more suitable strains of *Mannheimia haemolytica* (formerly *Pasteurella haemolytica*). This monograph applies to vaccines intended for administration to cattle of different ages for protection against respiratory diseases caused by *M. haemolytica*.

PRODUCTION

Production of the vaccine is based on a seed-lot system. The seed material is cultured in a suitable medium; each strain is cultivated separately and identity is verified using a suitable method. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity of the harvest are verified using suitable methods. After cultivation, the bacterial suspensions are collected separately and inactivated by a suitable method. The vaccine may contain an adjuvant and may be freeze-dried.

CHOICE OF VACCINE COMPOSITION

The choice of composition and the strains to be included in the vaccine is based on epidemiological data on the prevalence of the different serovars of *M. haemolytica* and on the claims being made. The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) in cattle. As part of the studies to demonstrate the suitability of the vaccine with respect to these characteristics the following tests may be carried out.

Safety

- A. The test is carried out for each route of administration to be stated on the label and in animals of each category for which the vaccine is intended.

For each test, use not fewer than 10 animals that preferably do not have antibodies against the serovars of *M. haemolytica* or against the leucotoxin present in the vaccine. Where justified, animals with a known history

of no previous mannheimia vaccination and with low antibody titres (measured in a sensitive test system such as an ELISA) may be used.

Administer to each animal a double dose of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine. Administer a single dose of vaccine to each animal after the recommended interval. Observe the animals for at least 14 days after the last administration. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each animal. No abnormal local or systemic reaction occurs; the average body temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C. If the vaccine is intended for use or may be used in pregnant cows, vaccinate the cows at the relevant stages of pregnancy and prolong the observation period until 1 day after parturition.

The vaccine complies with the test if no animal shows abnormal local or systemic reactions or clinical signs of disease or dies from causes attributable to the vaccine. In addition, if the vaccine is intended for use in pregnant cows, no significant effects on the pregnancy and offspring are demonstrated.

- B. The animals used for the field trials are also used to evaluate safety. Carry out a test in each category of animals for which the vaccine is intended. Use not fewer than 3 groups of 20 animals with corresponding groups of not fewer than 10 controls in 3 different locations. Examine the injection sites for local reactions after vaccination. Record body temperatures the day before vaccination, at vaccination and on the 2 days following vaccination. The vaccine complies with the test if no animal shows abnormal local or systemic reactions or clinical signs of disease or dies from causes attributable to the vaccine. The average body temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C. In addition, if the vaccine is intended for use in pregnant cows, no significant effects on the pregnancy and offspring are demonstrated.

Immunogenicity. As part of the studies to demonstrate the suitability of the vaccine with respect to immunogenicity, the test described under Potency may be carried out for each proposed route of administration and using vaccine of minimum potency.

BATCH TESTING

Batch potency test. The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to the results obtained with a batch of vaccine that has given satisfactory results in the test described under Potency.

Bacterial endotoxins. A test for bacterial endotoxins (2.6.14) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety test A given under Choice of vaccine composition or in the safety test described under Tests, carried out using 10 animals. Where the latter test is used, note the maximum temperature increase for each animal; the average body temperature increase for all animals does not exceed 1.5 °C. The method

01/2005:1946

chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for testing of each batch.

IDENTIFICATION

When injected into healthy seronegative animals, the vaccine stimulates the production of specific antibodies against the serovars of *M. haemolytica* and/or against the leucotoxin present in the vaccine.

TESTS

Safety. Use 2 cattle of the minimum age recommended for vaccination that have not been vaccinated against mannheimiosis. Administer a double dose of vaccine to each animal by a recommended route. Observe the animals for 14 days. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days. The animals remain in good health and no abnormal local or systemic reaction occurs; a transient temperature increase not exceeding 2 °C may occur.

Sterility. It complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

POTENCY

Carry out a test for each serovar for which protection is claimed on the label.

Use not fewer than 16 animals of the minimum age recommended for vaccination, free from antibodies against *M. haemolytica* and against the leucotoxin of *M. haemolytica*. Vaccinate not fewer than 8 of the animals by a recommended route and according to the recommended schedule. Keep 8 animals as controls. 21 days after the last vaccination, challenge all the animals by the intratracheal route or by another appropriate route, with a suitable quantity of a low-passage, virulent strain of a serovar of *M. haemolytica*. Observe the animals for a further 7 days; to avoid unnecessary suffering, severely ill animals are killed and are then considered to have died from the disease. During the observation period, the animals are examined for signs of disease for example, increased body temperature, dullness, abnormal breathing and the mortality is recorded. Kill surviving animals at the end of the observation period. Post-mortem examination is carried out on any animal that dies and those killed at the end of the observation period. The lungs are examined and the extent of lung lesions due to mannheimiosis is evaluated. Samples of lung tissue are collected for re-isolation of the challenge organisms. The clinical observations and lung lesions are scored and the results obtained for these parameters and the bacterial re-isolation results compared for the 2 groups.

The test is invalid if signs of *M. haemolytica* infection occur in less than 70 per cent of the control animals.

The vaccine complies with the requirements of the test if there is a significant difference between the scores obtained for the clinical and post-mortem observations in the vaccinates compared to the controls. For vaccines with a claim for a beneficial effect on the extent of infection against the serovar, the results for the infection rates are also significantly better for the vaccinates compared to the controls.

LABELLING

The label states:

- the serovar(s) of *M. haemolytica* against which protection is claimed,
- the serovar(s) of *M. haemolytica* and/or the leucotoxin present in the vaccine.

MANNHEIMIA VACCINE (INACTIVATED) FOR SHEEP

Vaccinum mannheimiae inactivatum ad ovem

DEFINITION

Mannheimia vaccine (inactivated) for sheep is a preparation of one or more suitable strains of *Mannheimia haemolytica* (formerly *Pasteurella haemolytica*). This monograph applies to vaccines intended for administration to sheep for active immunisation and to protect passively their future progeny against disease caused by *M. haemolytica*.

PRODUCTION

Production of the vaccine is based on a seed lot system. The seed material is cultured in a suitable medium; each strain is cultivated separately and identity is verified using a suitable method. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity of the harvest are verified using suitable methods. After cultivation, the bacterial suspensions are collected separately and inactivated by a suitable method. The vaccine may contain an adjuvant and may be freeze-dried.

CHOICE OF VACCINE COMPOSITION

The choice of composition and the strains to be included in the vaccine is based on epidemiological data on the prevalence of the different serovars of *M. haemolytica* and on the claims being made for the product, for example active and/or passive protection. The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) in sheep. As part of the studies to demonstrate the suitability of the vaccine with respect to these characteristics the following tests may be carried out.

Safety

- A. The test is carried out for each of the routes of administration to be stated on the label and in animals of each category (for example, young sheep, pregnant ewes) for which the vaccine is intended.

For each test, use not fewer than 10 animals that preferably do not have antibodies against the serovars of *M. haemolytica* or against the leucotoxin present in the vaccine. Where justified, animals with a known history of no previous mannheimia vaccination and with low antibody titres (measured in a sensitive test system such as an ELISA) may be used.

Administer to each animal a double dose of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine. Administer a single dose of vaccine to each animal after the recommended interval. Observe the animals for at least 14 days after the last administration. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each animal. No abnormal local or systemic reaction occurs; the average body temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C. If the vaccine is intended for use or may be used in pregnant ewes, vaccinate the ewes at the relevant stages of pregnancy and prolong the observation period until 1 day after lambing.

The vaccine complies with the test if no animal shows abnormal local reactions or clinical signs of disease or dies from causes attributable to the vaccine. In addition, if the vaccine is intended for use in pregnant ewes, no significant effects on the pregnancy and offspring are demonstrated.

- B. The animals used for the field trials are also used to evaluate safety. Carry out a test in each category of animals for which the vaccine is intended. Use not fewer than 3 groups of 20 animals with corresponding groups of not fewer than 10 controls in 3 different locations. Examine the injection sites for local reactions after vaccination. Record body temperatures the day before vaccination, at vaccination and on the 2 days following vaccination. The vaccine complies with the test if no animal shows abnormal local or systemic reactions or clinical signs of disease or dies from causes attributable to the vaccine. The average body temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C. In addition, if the vaccine is intended for use in pregnant ewes, no significant effects on the pregnancy and offspring are demonstrated.

Immunogenicity. As part of the studies to demonstrate the suitability of the vaccine with respect to immunogenicity, the tests described under Potency may be carried out for each proposed route of administration and using vaccine of minimum potency.

BATCH TESTING

Batch potency test. The relevant test or tests described under Potency are not carried out for routine testing of batches of vaccine. They are carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority. Where the relevant test or tests are not carried out, a suitable validated batch potency test is carried out, the criteria for acceptance being set with reference to the results obtained with a batch of vaccine that has given satisfactory results in the test(s) described under Potency.

Bacterial endotoxins. A test for bacterial endotoxins (2.6.14) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety test A given under Choice of vaccine composition or in the safety test described under Tests, carried out using 10 animals. Where the latter test is used, note the maximum temperature increase for each animal; the average body temperature increase for all animals does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for testing of each batch.

IDENTIFICATION

When injected into healthy seronegative animals, the vaccine stimulates the production of specific antibodies against the serovars of *M. haemolytica* and/or against the leucotoxin present in the vaccine.

TESTS

Safety. Use 2 sheep of the minimum age recommended for vaccination or, if not available, of an age as close as possible to the minimum recommended age, and that have not been vaccinated against mannheimiosis. Administer a double dose of vaccine to each animal by a recommended route. Observe the animals for 14 days. Record body temperature the day

before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days. The animals remain in good health and no abnormal local or systemic reaction occurs; a transient temperature increase not exceeding 2 °C may occur.

Sterility. It complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

POTENCY

Active immunisation. For vaccines with claims for active immunisation due to *M. haemolytica*, carry out a test for each serovar of *M. haemolytica* for which protection is claimed on the label.

Use not fewer than 20 lambs of the minimum age recommended for vaccination, free from antibodies against *M. haemolytica* and against the leucotoxin of *M. haemolytica*. Vaccinate not fewer than 10 of the animals by a recommended route and according to the recommended schedule. Keep 10 animals as controls. 21 days after the last vaccination, challenge all the lambs by the intratracheal route or by another appropriate route, with a suitable quantity of a low-passage, virulent strain of a serovar of *M. haemolytica*. Where necessary for a given serovar, prechallenge with parainfluenza type 3 (PI3) virus or another appropriate respiratory pathogen may be used. Observe the animals for a further 7 days; to avoid unnecessary suffering, severely ill animals are killed and are then considered to have died from the disease. During the observation period, the animals are examined for signs of disease (for example, increased body temperature, dullness, abnormal respiration) and the mortality is recorded. Kill surviving animals at the end of the observation period. Post-mortem examination is carried out on any animal that dies and those killed at the end of the observation period. The lungs are examined and the extent of lung lesions due to mannheimiosis is evaluated. Samples of lung tissue are collected for re-isolation of the challenge organisms. The clinical observations and lung lesions are scored and the results obtained for these parameters and the bacterial re-isolation results compared for the 2 groups.

The test is invalid if signs of *M. haemolytica* infection occur in less than 70 per cent of the control lambs.

The vaccine complies with the requirements of the test if there is a significant difference between the scores obtained for the clinical and post-mortem observations in the vaccinates compared to the controls. For vaccines with a claim for a beneficial effect on the extent of infection against the serovar, the results for the infection rates are also significantly better for the vaccinates compared to the controls.

Passive protection. For vaccines with claims for passive protection against mannheimiosis carry out a test for each serovar of *M. haemolytica* for which protection is claimed on the label.

Use at least 6 ewes that preferably do not have antibodies against the serovars of *M. haemolytica* or against the leucotoxin present in the vaccine. Where justified, animals with a known history of no previous mannheimia vaccination, from a source with a low incidence of respiratory disease and with low antibody titres (measured in a sensitive test system such as an ELISA) may be used. Vaccinate the animals by 1 of the recommended routes, at the recommended stages of pregnancy and according to the recommended schedule. A challenge study is conducted with 20 newborn, colostrum-deprived lambs. 10 of these lambs are given colostrum from the vaccinated ewes and 10 control lambs are given colostrum or colostrum substitute without detectable antibodies to *M. haemolytica*. When the lambs are at the age claimed for the duration of the passive protection, challenge by the intratracheal route with

a suitable quantity of a low-passage, virulent strain of a serovar of *M. haemolytica*. Observe the animals for a further 7 days; to avoid unnecessary suffering, severely ill animals are killed and are then considered to have died from the disease. Observe the animals and assess the effect of the challenge on the offspring of the vaccinates and the controls as described in the test for active immunisation.

The test is invalid if clinical signs or lesions of *M. haemolytica* infection occur in less than 70 per cent of the control lambs.

The vaccine complies with the requirements of the test if there is a significant difference between the scores obtained for the clinical and post-mortem observations in the lambs from the vaccinates compared to those from the controls. For vaccines with a claim for a beneficial effect on the extent of infection against the serovar, the results for the infection rates are also significantly better for the lambs from the vaccinates compared to those from the controls.

LABELLING

The label states:

- the serovar(s) of *M. haemolytica* against which protection is claimed,
- the serovar(s) of *M. haemolytica* and/or the leucotoxin present in the vaccine,
- for vaccines for passive protection, the length of time for which the passive protection is claimed.

01/2005:0589

MAREK'S DISEASE VACCINE (LIVE)

Vaccinum morbi Marek vivum

1. DEFINITION

Marek's disease vaccine (live) is a preparation of a suitable strain or strains of Marek's disease virus (gallid herpesvirus 2 or 3) and/or turkey herpesvirus (meleagrid herpesvirus 1). This monograph applies to vaccines intended for administration to chickens for active immunisation.

2. PRODUCTION

2-1. PREPARATION OF THE VACCINE

The vaccine virus is grown in cell cultures. If the vaccine contains more than 1 type of virus, the different types are grown separately. The vaccine may be freeze-dried or stored in liquid nitrogen.

2-2. SUBSTRATE FOR VIRUS PROPAGATION

2-2-1. **Cell cultures.** The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (5.2.4).

2-3. SEED LOTS

2-3-1. **Extraneous agents.** The master seed lot complies with the tests for extraneous agents in seed lots (2.6.24). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. CHOICE OF VACCINE VIRUS

The vaccine virus shall be shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) for the chickens for which it is intended.

The tests shown below for safety of the strain (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during the demonstration of safety and immunogenicity. Additional testing may be

needed to demonstrate safety in breeds of chickens known to be particularly susceptible to Marek's disease virus, unless the vaccine is to be contra-indicated.

2-4-1. **Safety.** Carry out the test for the route to be recommended for vaccination likely to be the least safe and in the category of chickens for which the vaccine is intended likely to be the most susceptible for Marek's disease. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. Use not fewer than eighty 1-day-old chickens from a flock free from specified pathogens (SPF) (5.2.2). Divide them randomly into 2 groups of not fewer than 40 chickens and maintain the groups separately. Carry out examination for macroscopic lesions of each chicken that dies and of the surviving chickens at the end of the observation periods. Administer to each chicken of one group (I) a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Administer by a suitable route to each chicken of the other group (II) a quantity of virulent Marek's disease virus that will cause mortality and/or severe macroscopic lesions of Marek's disease in not fewer than 70 per cent of the effective number of chickens within 70 days (initial number reduced by the number that die within the first 7 days of the test). Observe the chickens of group II at least daily for 70 days and those of group I at least daily for 120 days. The test is not valid if 1 or more of the following apply: more than 10 per cent of the chickens in any group die within the first 7 days of the test; fewer than 70 per cent of the effective number of chickens in group II show macroscopic lesions of Marek's disease. The vaccine virus complies with the test if:

- no chicken of group I shows notable clinical signs or macroscopic lesions of Marek's disease or dies from causes attributable to the vaccine virus,
- at 120 days the number of surviving chickens of group I is not fewer than 80 per cent of the effective number.

2-4-2. **Increase in virulence.** The test for increase in virulence is required for Marek's disease virus vaccine strains but not for turkey herpesvirus vaccine strains, which are naturally apathogenic. Administer by the intramuscular route a quantity of the vaccine virus that will allow recovery of virus for the passages described below to each of five 1-day-old chickens from an SPF flock (5.2.2). Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. Prepare 5 to 7 days later a suspension of white blood cells of each chicken and pool these samples. Administer a suitable volume of the pooled samples by the intraperitoneal route to each of 5 other chickens that are 1-day-old and from an SPF flock (5.2.2). Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. Care must be taken to avoid contamination by virus from previous passages. If the virus is not found at a passage level, carry out a second series of passages. Carry out the safety test (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged virus that has been recovered. Administer the virus by the route to be recommended for vaccination likely to be the least safe for use in these birds. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. **Immunogenicity.** A test is carried out for each route and method of administration to be recommended using in each case chickens of the youngest age to be recommended for vaccination. The quantity of the vaccine

virus administered to each chicken is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. Use for the test not fewer than 60 chickens of the same origin and from an SPF flock (5.2.2). Vaccinate by a recommended route not fewer than 30 chickens. Maintain not fewer than 30 chickens as controls. Challenge each chicken after 9 days by a suitable route with a sufficient quantity of virulent Marek's disease virus. Observe the chickens at least daily for 70 days after challenge. Record the deaths and the number of surviving chickens that show clinical signs of disease. At the end of the observation period kill all the surviving chickens and carry out examination for macroscopic lesions of Marek's disease. The test is not valid if:

- during the observation period after challenge fewer than 70 per cent of the control chickens die or show severe clinical signs or macroscopic lesions of Marek's disease,
- and/or during the period between the vaccination and challenge more than 10 per cent of the control or vaccinated chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if the percentage relative protection, calculated using the following expression, is not less than 80 per cent:

$$\frac{V - C}{100 - C} \times 100$$

- V* = percentage of challenged vaccinated chickens that survive to the end of the observation period without notable clinical signs or macroscopic lesions of Marek's disease,
- C* = percentage of challenged control chickens that survive to the end of the observation period without notable clinical signs or macroscopic lesions of Marek's disease.

3. BATCH TESTS

3-1. Identification. Carry out an immunostaining test in cell cultures using monoclonal antibodies to demonstrate the presence of each type of virus stated on the label.

3-2. Bacteria and fungi. The vaccine and, where applicable, the liquid supplied with it comply with the requirement for sterility prescribed in the monograph *Vaccines for veterinary use* (0062).

3-3. Mycoplasmas. The vaccine complies with the test for mycoplasmas (2.6.7).

3-4. Extraneous agents. The vaccine complies with the tests for extraneous agents in batches of finished product (2.6.25).

3-5. Safety. Use not fewer than 10 chickens from an SPF flock (5.2.2) and not older than the youngest age recommended for vaccination. Administer by a recommended route and method to each chicken 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. Virus titre

3-6-1 Vaccines containing one type of virus. Titrate the vaccine virus by inoculation into suitable cell cultures (5.2.4). If the virus titre is determined in plaque-forming units (PFU), only primary plaques are taken into consideration. The

vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-6-2. Vaccines containing more than one type of virus. For vaccines containing more than 1 type of virus, titrate each virus by inoculation into suitable cell cultures (5.2.4), reading the results by immunostaining using antibodies. The vaccine complies with the test if 1 dose contains for each vaccine virus not less than the minimum virus titre stated on the label.

3-7. Potency. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-4-3) when administered according to the recommended schedule by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2005:1943

MYXOMATOSIS VACCINE (LIVE) FOR RABBITS

*Vaccinum myxomatosis vivum
ad cuniculum*

DEFINITION

Myxomatosis vaccine (live) for rabbits is a preparation of a suitable strain of either myxoma virus that is attenuated for rabbits or Shope fibroma virus. The vaccine is intended for the active immunisation of rabbits against myxomatosis.

PRODUCTION

The virus is propagated in suitable cell cultures (5.2.4). The viral suspension is harvested, titrated and may be mixed with a suitable stabilising solution. The vaccine may be freeze-dried.

CHOICE OF VACCINE STRAIN

The vaccine is shown to be satisfactory with respect to safety, absence of increase in virulence and immunogenicity. The following tests may be used during demonstration of safety, absence of increase in virulence (5.2.6) and efficacy (5.2.7). **Safety.** The test is carried out for each route of administration to be stated on the label. Use at least 10 rabbits of the minimum age to be recommended for vaccination and that do not have antibodies against myxoma virus. Administer to each rabbit by a recommended route a quantity of virus corresponding to not less than 10 times the maximum titre that may be expected in a dose of vaccine. Observe the rabbits for 28 days. Record the body temperature the day before vaccination, at vaccination, 4 h after vaccination and then daily for 4 days; note the maximum temperature increase for each animal. No abnormal local or systemic reaction occurs; the average temperature increase does not exceed 1 °C and no animal shows a rise greater than 2 °C. A local reaction lasting less than 28 days may occur.

If the vaccine is intended for use in pregnant rabbits, administer the virus to not less than 10 pregnant rabbits according to the schedule to be recommended on the label. Prolong the observation period until 1 day after parturition. The rabbits remain in good health and there is no abnormal local or systemic reaction. No adverse effects on the pregnancy or the offspring are noted.

Increase in virulence. (This test is performed only for vaccines based on attenuated strains of myxoma virus). Administer by a recommended route to each of 2 rabbits, 5 to 7 weeks old and which do not have antibodies against

myxoma virus, a quantity of virus that will allow recovery of virus for the passages described below. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. Kill the rabbits 5 to 10 days after inoculation and remove from each rabbit organs, or tissues with sufficient virus to allow passage; homogenise the organs and tissues in a suitable buffer solution, centrifuge the suspension and use the supernatant for further passages. Inoculate the supernatant into suitable cell cultures to verify the presence of virus. Administer by an appropriate route, at a suitable rate, a suitable volume of the supernatant to each of 2 other rabbits of the same age and the same susceptibility. This operation is then repeated at least 5 times. If the virus has disappeared, a second series of passages is carried out. Inoculate virus from the highest recovered passage level to rabbits, observe for 28 days and compare any reactions that occur with those seen in the test for safety described above. There is no indication of an increase in virulence as compared with the non-passaged virus. If virus is not recovered in either of 2 series of passages, the vaccine virus also complies with the test.

Immunogenicity. The test described under Potency may be used to demonstrate the immunogenicity of the strain.

BATCH POTENCY TEST

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, using a vaccinating dose containing not more than the minimum virus titre stated on the label, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot.

IDENTIFICATION

Carry out an immunofluorescence test in suitable cell cultures, using a monospecific antiserum.

TESTS

Safety. Use not fewer than 2 rabbits, not older than the minimum age recommended for vaccination, that do not have antibodies against myxoma virus and rabbit haemorrhagic disease virus and that have been reared in suitable isolation conditions to avoid contact with myxoma virus. Administer by a recommended route to each rabbit 10 doses of vaccine. Observe the rabbits at least daily for 14 days. No abnormal local or systemic reaction occurs.

Extraneous agents. At the end of the 14 day observation period of the safety test, administer by a recommended route to each rabbit, a further 10 doses of vaccine. After 14 days take a blood sample from each rabbit and carry out a test for antibodies against rabbit haemorrhagic disease virus. No antibodies are found.

Bacterial and fungal contamination. The vaccine, reconstituted if necessary, complies with the test for sterility prescribed in the monograph on *Vaccines for Veterinary Use* (0062).

Mycoplasmas (2.6.7). The vaccine, reconstituted if necessary, complies with the test for mycoplasmas.

Virus titre. Reconstitute the vaccine, if necessary, and titrate in suitable cell cultures. 1 dose of the vaccine contains not less than the quantity of virus equivalent to the minimum virus titre stated on the label.

POTENCY

Use not fewer than 15 susceptible rabbits of the minimum age to be recommended for vaccination, free from antibodies against myxoma virus and reared in suitable isolation conditions to ensure absence of contact with myxoma virus.

Administer 1 dose of vaccine to each of not fewer than 10 of the rabbits according to the instructions for use. Keep not less than 5 other rabbits as controls. Not less than 21 days after the last vaccination, administer by a suitable route to each rabbit a quantity of a virulent strain of myxoma virus sufficient to cause typical signs of myxomatosis in a susceptible rabbit. Observe the rabbits for a further 21 days. The test is not valid if fewer than 90 per cent of the control rabbits display typical signs of myxomatosis. A vaccine containing myxoma virus complies with the test if not fewer than 90 per cent of vaccinated rabbits show no signs of myxomatosis. A vaccine containing Shope fibroma virus complies with the test if not fewer than 75 per cent of vaccinated rabbits show no signs of myxomatosis.

LABELLING

The label states, where applicable, that a local reaction may occur.

01/2005:0962

NEONATAL PIGLET COLIBACILLOSIS VACCINE (INACTIVATED)

Vaccinum colibacillosis fetus a partu recentis inactivatum ad suem

DEFINITION

Neonatal piglet colibacillosis vaccine (inactivated) is prepared from cultures of one or more suitable strains of *Escherichia coli*, carrying one or more adhesins or enterotoxins. This monograph applies to vaccines administered by injection to sows and gilts for protection of newborn piglets against enteric forms of colibacillosis.

PRODUCTION

The *E. coli* strains used for production are cultured separately in a suitable medium. The cells or toxins are processed to render them safe and are blended.

The vaccine may contain one or more suitable adjuvants.

CHOICE OF VACCINE COMPOSITION

The *E. coli* strains used in the production of the vaccine are shown to be satisfactory with respect to expression of antigens and the vaccine is shown to be satisfactory with respect to safety and immunogenicity. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Expression of antigens. The expression of antigens that stimulate a protective immune response is verified by a suitable immunochemical method (2.7.1) carried out on the antigen obtained from each of the vaccine strains under the conditions used for the production of the vaccine.

Safety

A. Administer a double dose of vaccine by a recommended route to each of not fewer than 10 pregnant sows that have not been vaccinated against colibacillosis. Administer 1 dose of vaccine to each of the animals after the recommended interval. Observe the animals until farrowing. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each animal. Note any effects on gestation or the offspring. No abnormal local or systemic reaction occurs: the average temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C.

B. The animals used for field trials are also used to evaluate safety. Use not fewer than 3 groups each of not fewer than 20 animals with corresponding groups of not fewer than 10 controls. Examine the injection site for local reactions after vaccination. Record body temperature the day before vaccination, at vaccination, at the time interval after which a rise in temperature, if any, was seen in test A, and daily during the 2 days following vaccination; note the maximum temperature increase for each animal. No abnormal local or systemic reaction occurs: the average temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C.

Immunogenicity. The suitability of the vaccine with respect to immunogenicity may be demonstrated by the test described under Potency.

BATCH TESTING

Batch potency test. *The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a suitable correlation with the test described under Potency has been established by a statistical evaluation.*

Use pigs not less than 3 weeks old and free from specific antibodies against the antigens stated on the label: vaccinate each of 5 pigs by the route and according to the schedule stated on the label. Maintain 2 pigs as unvaccinated controls. Alternatively, if the nature of the antigens allows reproducible results to be obtained, a test in laboratory animals (for example, guinea-pigs, mice, rabbits or rats) may be carried out. To obtain a valid assay, it may be necessary to carry out a test using several groups of animals, each receiving a different dose. For each dose, carry out the test as follows. Vaccinate not fewer than 5 animals with a single injection of a suitable dose. Maintain not fewer than 2 animals as unvaccinated controls. Where the schedule stated on the label requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval within the range of 14 to 21 days after the last injection, collect blood from each animal and prepare serum samples. Use a suitable validated test such as an enzyme-linked immunosorbent assay (2.7.1) to measure the antibody response to each of the antigens stated on the label. The antibody levels are not significantly less than those obtained with a batch that has given satisfactory results in the test described under Potency and there is no significant increase in antibody titre in the controls.

Where seronegative animals are not available, seropositive animals may be used in the above test. During the development of a test with seropositive animals, particular care will be required during the validation of the test system to establish that the test is suitably sensitive and to specify acceptable pass, fail and retest criteria. It will be necessary to take into account the range of possible prevaccination titres and establish the acceptable minimum titre rise after vaccination in relation to these.

Bacterial endotoxins. A test for bacterial endotoxins (2.6.14) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable

amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety test A given under Choice of vaccine composition or in the safety test described under Tests, carried out using 10 piglets. Where the latter test is used, note the maximum temperature increase for each animal; the average temperature increase for all animals does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for testing of each batch.

IDENTIFICATION

In animals free from specific antibodies against the antigens stated on the label, the vaccine stimulates the production of antibodies against these antigens.

TESTS

Safety. Use pigs preferably having no specific antibodies against the antigens stated on the label or, where justified, pigs with a low level of such antibodies as long as they have not been vaccinated against colibacillosis and administration of the vaccine does not cause an anamnestic response. Administer to each of 2 pigs a double dose of vaccine by a recommended route. Observe the animals for 14 days. Record body temperature before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days. No abnormal local or systemic reaction occurs; a transient temperature increase not exceeding 2 °C may occur.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Carry out the test with a challenge strain representing each type of antigen against which the vaccine is intended to protect: if a single strain with all the necessary antigens is not available, repeat the test using different challenge strains.

Use not fewer than 8 susceptible gilts free from specific antibodies against the antigens stated on the label. Take not fewer than 4 at random and vaccinate these at the stage of pregnancy and according to the recommended vaccination scheme. Within 12 h of their giving birth, take not fewer than 15 healthy piglets from the vaccinated animals and 15 healthy piglets from the unvaccinated controls, taking at least 3 from each litter. Challenge all the piglets orally with a pathogenic strain of *E. coli* before or after colostrum feeding and using the same conditions for vaccinated animals and controls. The strain used must not be one used in the manufacture of the vaccine. Return the piglets to their dam and observe for 8 days.

On each day, note clinical signs in each piglet and score using the following scale:

- | | |
|---|----------------------------------|
| 0 | no signs |
| 1 | slight diarrhoea |
| 2 | marked diarrhoea (watery faeces) |
| 3 | dead |

Total scores for each piglet over 8 days are calculated. The test is not valid unless at least 40 per cent of the piglets from the control animals die and not more than 15 per cent of the piglets from the control animals show no signs of illness. The vaccine complies with the test if there is a significant reduction in score in the group of piglets from the vaccinated gilts compared with the group from the unvaccinated controls.

For some adhesins (for example, F5 and F41), there is published evidence that high mortality cannot be achieved under experimental conditions. If challenge has to be carried out with a strain having such adhesins: the test is not valid if fewer than 70 per cent of the control piglets show clinical signs expected with the challenge strain; the vaccine complies with the test if there is a significant reduction in score in the group of piglets from the vaccinated gilts compared with the group from the unvaccinated controls.

LABELLING

The label states the antigen or antigens contained in the vaccine that stimulate a protective immune response.

01/2005:0961

NEONATAL RUMINANT COLIBACILLOSIS VACCINE (INACTIVATED)

*Vaccinum colibacillosis fetus a partu
recentis inactivatum ad ruminantes*

DEFINITION

Neonatal ruminant colibacillosis vaccine (inactivated) is prepared from cultures of one or more suitable strains of *Escherichia coli*, carrying one or more adhesin factors or enterotoxins. This monograph applies to vaccines administered by injection to dams for protection of newborn offspring against enteric forms of colibacillosis.

PRODUCTION

The *E. coli* strains used for production are cultured separately in a suitable medium. The cells or toxins are processed to render them safe and are blended.

The vaccine may contain one or more suitable adjuvants.

CHOICE OF VACCINE COMPOSITION

The *E. coli* strains used in the production of the vaccine are shown to be satisfactory with respect to expression of antigens and the vaccine is shown to be satisfactory with respect to safety and immunogenicity. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Expression of antigens. The expression of antigens that stimulate a protective immune response is verified by a suitable immunochemical method (2.7.1) carried out on the antigen obtained from each of the vaccine strains under the conditions used for the production of the vaccine.

Safety

- A. A double dose of vaccine is administered to each of 10 pregnant animals of each of the species for which the vaccine is intended and that have not been vaccinated against colibacillosis. 1 dose is administered to each animal after the interval stated on the label. The animals are observed until parturition has occurred. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each animal. No abnormal local or systemic reaction occurs; the average temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C. Any effects on gestation or the offspring are noted.
- B. Safety is demonstrated in field trials for each species for which the vaccine is intended by administering the intended dose to at least 60 animals from 3 different

stocks, by the route and according to the schedule stated on the label. At least 30 animals from the same stocks are assigned to control groups. The animals are observed for 14 days after the last dose. No abnormal local or systemic reaction is noted and, in particular, no rise in temperature of more than 1.5 °C occurs within 2 days of administration of each dose of vaccine.

Immunogenicity. The suitability of the vaccine with respect to immunogenicity must be demonstrated for each species for which it is intended. This may be demonstrated by the test described under Potency.

BATCH TESTING

Batch potency test. *The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a suitable correlation with the test described under Potency has been established by a statistical evaluation.*

To obtain a valid assay, it may be necessary to carry out a test using several groups of animals, each receiving a different dose. For each dose required, carry out the test as follows. Vaccinate not fewer than 5 animals (for example rabbits, guinea-pigs, rats or mice), free from specific antibodies against the antigens stated on the label, using one injection of a suitable dose. Maintain 2 animals as unvaccinated controls. Where the schedule stated on the label requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval within the range of 14 to 21 days after the last injection, collect blood from each animal and prepare serum samples. Use a suitable validated test such as an enzyme-linked immunosorbent assay (2.7.1) to measure the antibody response to each of the protective antigens stated on the label. The antibody levels are not significantly less than those obtained with a batch that has given satisfactory results in the test described under Potency and there is no significant increase in antibody titre in the controls.

Where seronegative animals are not available, seropositive animals may be used in the above test. During the development of a test with seropositive animals, particular care will be required during the validation of the test system to establish that the test is suitably sensitive and to specify acceptable pass, fail and retest criteria. It will be necessary to take into account the range of possible prevaccination titres and establish the acceptable minimum titre rise after vaccination in relation to these.

Bacterial endotoxins. A test for bacterial endotoxins (2.6.14) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety test A given under Choice of vaccine composition or in the safety test described under Tests, carried out using 10 animals. Where the latter test is used, note the maximum temperature increase for each animal; the average temperature increase for all animals does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present

in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxins is used subsequently for testing of each batch.

01/2005:0870

IDENTIFICATION

In animals free from specific antibodies against the antigens stated on the label, the vaccine stimulates the production of antibodies against these antigens.

TESTS

Safety. Use animals of one of the species for which the vaccine is recommended and preferably having no specific antibodies against the antigens stated on the label or, where justified, use animals with a low level of such antibodies as long as they have not been vaccinated against colibacillosis and administration of the vaccine does not cause an anamnestic response. Administer by a recommended route a double dose of vaccine to each of 2 animals. Observe the animals for 14 days. Record body temperature before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days. No abnormal local or systemic reaction occurs; a transient temperature increase not exceeding 2 °C may occur.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Carry out the test with a challenge strain representing each type of antigen against which the vaccine is intended to protect: if a single strain with all the necessary antigens is not available, repeat the test using different challenge strains.

Use not fewer than 15 susceptible animals of one of the species for which the vaccine is recommended and which are free from specific antibodies against the antigens stated on the label. Take not fewer than 10 at random and vaccinate these at the recommended stage of pregnancy and according to the recommended schedule. Collect colostrum from all animals after parturition and store the samples individually in conditions that maintain antibody levels. Take not fewer than 15 newborn unsuckled animals and house them in an environment ensuring absence of enteric pathogens. Allocate a colostrum sample from not fewer than 10 vaccinated dams and not fewer than 5 controls to the offspring. After birth, feed the animals with the colostrum sample allocated to it. After feeding the colostrum and within 12 h of birth, challenge the animals orally with a pathogenic strain of *E. coli* and observe for 10 days. The strain must not be one used in the manufacture of the vaccine.

On each day, note clinical signs in each animal and score using the following scale:

- 0 no signs
- 1 slight diarrhoea
- 2 marked diarrhoea (watery faeces)
- 3 dead

Total scores for each animal over 10 days are calculated. The test is not valid unless 80 per cent of the offspring from the control animals die or show severe signs of disease. The vaccine complies with the test if there is a significant reduction in score in the group of animals from vaccinated dams compared with the group from the unvaccinated controls.

LABELLING

The label states the antigen or antigens contained in the vaccine that stimulate a protective immune response.

NEWCASTLE DISEASE VACCINE (INACTIVATED)

Vaccinum pseudopestis aviariae inactivatum

DEFINITION

Newcastle disease vaccine (inactivated) [also known as avian paramyxovirus 1 vaccine (inactivated) for vaccines intended for some species] consists of an emulsion or a suspension of a suitable strain of Newcastle disease virus (avian paramyxovirus 1) that has been inactivated in such a manner that immunogenic activity is retained.

PRODUCTION

The virus is propagated in embryonated eggs from healthy flocks or in suitable cell cultures (5.2.4).

The test for inactivation is carried out in embryonated eggs or suitable cell cultures and the quantity of inactivated virus used is equivalent to not less than ten doses of vaccine. No live virus is detected.

The vaccine may contain an adjuvant.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and immunogenicity (5.2.7) for each species and category of birds for which it is intended. The following tests may be used during demonstration of immunogenicity.

Immunogenicity. For domestic fowl, the test with virulent challenge (test B) described under Potency is suitable for demonstrating immunogenicity. For other species of birds (for example, pigeons or turkeys), test C described under Potency is suitable for demonstrating immunogenicity.

BATCH TESTING

Batch potency test

For vaccines used in domestic fowl, carry out test A described under Potency but, if the nature of the product does not allow valid results to be obtained with test A or if the batch does not comply with test A, carry out test B. A test using fewer than twenty birds per group and a shorter observation period after challenge may be used if this has been shown to give a valid potency test.

For vaccines used in species other than domestic fowl, carry out a suitable validated test for which a satisfactory correlation has been established with test C described under Potency, the criteria for acceptance being set with reference to a batch that has given satisfactory results in the latter test. A test in chickens from a flock free from specified pathogens (5.2.2) and consisting of a measure of the serological response to graded amounts of vaccine (for example, 1/25, 1/50 and 1/100 dose with serum sampling 17 to 21 days later) may be used.

IDENTIFICATION

When injected into animals free from antibodies against Newcastle disease virus, the vaccine stimulates the production of such antibodies.

TESTS

Safety. If the vaccine is intended for use in domestic fowl, vaccinate ten chickens from a flock free from specified pathogens (5.2.2). If the vaccine is not for use in domestic fowl, use ten birds of one of the species for which the vaccine is intended, free from antibodies against Newcastle disease virus. Inject twice the vaccinating dose by a recommended

route into each of ten birds, 14 to 28 days old. Observe the birds for 21 days. No abnormal local or systemic reaction occurs.

Inactivation. Inject two-fifths of a dose into the allantoic cavity of each of ten embryonated hen eggs, 9 to 11 days old, from flocks free from specified pathogens (5.2.2) (SPF eggs) and incubate. Observe for 6 days and pool separately the allantoic fluid from eggs containing live embryos, and that from eggs containing dead embryos, excluding those dying within 24 h of the injection. Examine embryos that die within 24 h of injection for the presence of Newcastle disease virus: the vaccine does not comply with the test if Newcastle disease virus is found.

Inject into the allantoic cavity of each of ten SPF eggs, 9 to 11 days old, 0.2 ml of the pooled allantoic fluid from the live embryos and, into each of ten similar eggs, 0.2 ml of the pooled fluid from the dead embryos and incubate for 5 to 6 days. Test the allantoic fluid from each egg for the presence of haemagglutinins using chicken erythrocytes.

The vaccine complies with the test if there is no evidence of haemagglutinating activity and if not more than 20 per cent of the embryos die at either stage. If more than 20 per cent of the embryos die at one of the stages, repeat that stage; the vaccine complies with the test if there is no evidence of haemagglutinating activity and not more than 20 per cent of the embryos die at that stage.

Antibiotics may be used in the test to control extraneous bacterial infection.

Extraneous agents. Inject a double dose by a recommended route into each of ten chickens, 14 to 28 days old and from a flock free from specified pathogens (5.2.2). After 3 weeks, inject one dose by the same route. Collect serum samples from each chicken 2 weeks later and carry out tests for antibodies to the following agents by the methods prescribed for chicken flocks free from specified pathogens (5.2.2): avian encephalomyelitis virus, avian infectious bronchitis virus, avian leucosis viruses, egg-drop syndrome virus, avian bursal disease virus, avian infectious laryngotracheitis virus, influenza A virus, Marek's disease virus. The vaccine does not stimulate the formation of antibodies against these agents.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

For vaccines for use in domestic fowl carry out test A. If an unsatisfactory result is obtained with test A but a satisfactory result is obtained with test B, the vaccine complies with the requirements. For vaccines for use only in other species, such as pigeons, carry out test C.

A. Inject intramuscularly into each of not fewer than ten chickens, 21 to 28 days old and from a flock free from specified pathogens (5.2.2), a volume of the vaccine equivalent to 1/50 of a dose. 17 to 21 days later, collect serum samples from each vaccinated chicken and from each of not fewer than five control chickens of the same age and from the same source. Measure the antibody levels in the sera by the haemagglutination-inhibition (HI) test using the technique described below or an equivalent technique with the same numbers of

haemagglutinating units and red blood cells. The test system used must include negative and positive control sera, the latter having an HI titre of 5.0 log₂ to 6.0 log₂.

The vaccine complies with the test if the mean HI titre of the vaccinated group is equal to or greater than 4.0 log₂ and that of the unvaccinated group is 2.0 log₂ or less. If the HI titres are not satisfactory, carry out test B.

Haemagglutination-inhibition test. Inactivate the test sera by heating at 56 °C for 30 min. Add 0.025 ml to the first row of wells in a microtitre plate. Add 0.025 ml of a buffered 9 g/l solution of *sodium chloride R* at pH 7.2 to pH 7.4 to the rest of the wells. Prepare twofold dilutions of the sera across the plate. To each well add 0.025 ml of a suspension containing 4 haemagglutinating units of inactivated Newcastle disease virus. Incubate the plate at 4 °C for 1 h. Add 0.025 ml of a 1 per cent V/V suspension of red blood cells collected from chickens, 3 to 4 weeks old and free from antibodies against Newcastle disease virus. Incubate the plate at 4 °C for 1 h. The HI titre is equal to the highest dilution that produces complete inhibition.

- B. Use chickens 21 to 28 days old and from a flock free from specified pathogens (5.2.2). For vaccination, use not fewer than three groups, each of not fewer than twenty chickens; keep a group of ten chickens as controls. Choose a number of different volumes of the vaccine corresponding to the number of groups: for example, volumes equivalent to 1/25, 1/50 and 1/100 of a dose. Allocate a different volume to each vaccination group. Inject intramuscularly into each chicken the volume of vaccine allocated to its group. 17 to 21 days later, challenge all the chickens by intramuscular injection of 6 log₁₀ embryo LD₅₀ of the Herts (Weybridge 33/56) strain of Newcastle disease virus. Observe the chickens for 21 days. Calculate the PD₅₀ by standard statistical methods from the number of chickens that survive in each vaccinated group without showing any clinical evidence of Newcastle disease during the 21 days. The vaccine complies with the test if the smallest dose stated on the label corresponds to not less than 50 PD₅₀ and the lower confidence limit is not less than 35 PD₅₀ per dose. If the lower confidence limit is less than 35 PD₅₀ per dose, repeat the test; the vaccine must be shown to contain not less than 50 PD₅₀ in the repeat test. The test is not valid unless all the control birds die within 6 days of challenge.
- C. Vaccinate not fewer than twenty birds of the target species, free from antibodies against avian paramyxovirus 1, in accordance with the recommendations for use. Maintain as unvaccinated controls a group of not fewer than ten birds of the same age, from the same source and free from antibodies against avian paramyxovirus 1. The test is invalid if serum samples obtained at the time of the first vaccination show the presence of antibodies against avian paramyxovirus 1 in either vaccinates or controls or if tests carried out at the time of challenge show such antibodies in controls. 4 weeks after the last vaccination, challenge each bird intramuscularly with a sufficient quantity of virulent avian paramyxovirus 1. The test is not valid if fewer than 90 per cent of the control birds die or show serious signs of Newcastle disease virus infection. The vaccine complies with the test if not fewer than 90 per cent of the vaccinated birds survive and show no serious signs of avian paramyxovirus 1 infection.

01/2005:0450

NEWCASTLE DISEASE VACCINE (LIVE)

Vaccinum pseudopestis aviariae vivum

1. DEFINITION

Newcastle disease vaccine (live) is a preparation of a suitable strain of Newcastle disease virus (avian paramyxovirus 1). This monograph applies to vaccines intended for administration to chickens and/or other avian species for active immunisation.

2. PRODUCTION

2-1. PREPARATION OF THE VACCINE

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. SUBSTRATE FOR VIRUS PROPAGATION

2-2-1. **Embryonated hens' eggs.** If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (5.2.2).

2-2-2. **Cell cultures.** If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (5.2.4).

2-3. SEED LOTS

2-3-1. **Extraneous agents.** The master seed lot complies with the tests for extraneous agents in seed lots (2.6.24). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. CHOICE OF VACCINE VIRUS

The vaccine virus shall be shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) for the birds for which it is intended.

The following tests for intracerebral pathogenicity index (section 2-4-1), amino-acid sequence (section 2-4-2), safety (section 2-4-3), increase in virulence (section 2-4-4) and immunogenicity (section 2-4-5) may be used during the demonstration of safety and immunogenicity.

2-4-1. **Intracerebral pathogenicity index.** Use vaccine virus at the least attenuated passage level that will be present in a batch of the vaccine. Inoculate the vaccine virus into the allantoic cavity of embryonated hens' eggs, 9- to 11- days-old, from an SPF flock (5.2.2). Incubate the inoculated eggs for a suitable period and harvest and pool the allantoic fluids. Use not fewer than ten 1-day-old chickens (i.e. more than 24 h but less than 40 h after hatching), from an SPF flock (5.2.2). Administer by the intracerebral route to each chick 0.05 ml of the pooled allantoic fluids containing not less than $10^{8.0}$ EID₅₀ or, if this virus quantity cannot be achieved, not less than $10^{7.0}$ EID₅₀. Observe the chickens at least daily for 8 days after administration and score them once every 24 h. A score of 0 is attributed to a chicken if it is clinically normal, 1 if it shows clinical signs of disease and 2 if it is dead. The intracerebral pathogenicity index is the mean of the scores per chicken per observation over the 8 day period.

If an inoculum of not less than $10^{8.0}$ EID₅₀ is used, the vaccine virus complies with the test if its intracerebral pathogenicity index is not greater than 0.5; if an inoculum of not less than $10^{7.0}$ EID₅₀ but less than $10^{8.0}$ EID₅₀ is used, the vaccine virus complies with the test if its intracerebral pathogenicity index is not greater than 0.4.

2-4-2. **Amino-acid sequence.** Determine the sequence of a fragment of RNA from the vaccine virus containing the region encoding for the F0 cleavage site by a suitable method. The encoded amino-acid sequence is shown to be one of the following:

	F2						Cleavage site	F1		
Site	111	112	113	114	115	116	∇	117	118	119
	Gly	Gly	Lys	Gln	Gly	Arg		Leu	Ile	Gly
or	Gly	Gly	Arg	Gln	Gly	Arg		Leu	Ile	Gly
or	Gly	Glu	Arg	Gln	Glu	Arg		Leu	Val	Gly

or equivalent with leucine at 117 and no basic amino acids at sites 111, 112, 114 and 115.

2-4-3. **Safety.** Carry out the test for each route and method of administration to be recommended for vaccination and in each avian species for which the vaccine is intended, using in each case birds not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For tests in chickens, use not fewer than 20 chickens, from an SPF flock (5.2.2). For species other than the chicken, use not fewer than 20 birds that do not have antibodies against Newcastle disease virus. Administer to each bird a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Observe the birds at least daily for 21 days. The test is not valid if more than 10 per cent of the birds show abnormal clinical signs or die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no bird shows notable clinical signs of Newcastle disease or dies from causes attributable to the vaccine virus.

2-4-4. **Increase in virulence.** The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to a group of 5 birds not more than 2 weeks old, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Carry out the test in a target species, using the chicken if it is one of the target species. For the test in chickens, use chickens from an SPF flock (5.2.2). For other species, carry out the test in birds that do not have antibodies against Newcastle disease virus. Administer by eye-drop a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Observe the birds for the period shown to correspond to maximum replication of the vaccine virus, kill them and prepare a suspension from the brain of each bird and from a suitable organ depending on the tropism of the strain (for example, mucosa of the entire trachea, intestine, pancreas); pool the samples. Administer 0.05 ml of the pooled samples by eye-drop to each of 5 other birds of the same species, age and origin. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

A. Carry out the test for intracerebral pathogenicity index (section 2-4-1) using unpassaged vaccine virus and the maximally passaged virus that has been recovered.

- B. Carry out the test for amino-acid sequence (section 2-4-2) using unpassaged vaccine virus and the maximally passaged virus that has been recovered.
- C. Carry out the test for safety (section 2-4-3) using unpassaged vaccine virus and the maximally passaged virus that has been recovered. Administer the virus by the route to be recommended for vaccination likely to be the least safe and to the avian species for which the vaccine is intended that is likely to be the most susceptible to Newcastle disease.

The vaccine virus complies with the test if, in the tests 2-4-4A, 2-4-4B and 2-4-4C, no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-5. Immunogenicity. For each avian species for which the vaccine is intended, a test is carried out for each route and method of administration to be recommended using in each case birds not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each bird is not greater than the minimum titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine.

2-4-5-1. Vaccines for use in chickens. Use not fewer than 30 chickens of the same origin and from an SPF flock (5.2.2). Vaccinate by a recommended route not fewer than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 21 days by the intramuscular route with not less than $10^{5.0}$ embryo LD₅₀ of the Herts (Weybridge 33/56) strain of Newcastle disease virus. Observe the chickens at least daily for 14 days after challenge. Record the deaths and the number of surviving chickens that show clinical signs of disease. The test is not valid if 6 days after challenge fewer than 100 per cent of the control chickens have died or if during the period between vaccination and challenge more than 10 per cent of the vaccinated or control chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine virus complies with the test if during the observation period after challenge not fewer than 90 per cent of the vaccinated chickens survive and show no notable clinical signs of Newcastle disease.

2-4-5-2. Vaccines for use in avian species other than the chicken. Use not fewer than 30 birds of the species for which the vaccine is intended for Newcastle disease, of the same origin and that do not have antibodies against avian paramyxovirus 1. Vaccinate by a recommended route not fewer than 20 birds. Maintain not fewer than 10 birds as controls. Challenge each bird after 21 days by the intramuscular route with a sufficient quantity of virulent avian paramyxovirus 1. Observe the birds at least daily for 21 days after challenge. Record the deaths and the surviving birds that show clinical signs of disease. The test is not valid if:

- during the observation period after challenge fewer than 90 per cent of the control birds die or show severe clinical signs of Newcastle disease,
- or if during the period between the vaccination and challenge more than 10 per cent of the vaccinated or control birds show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not fewer than 90 per cent of the vaccinated birds survive and show no notable clinical signs of Newcastle disease. For species where there

is published evidence that it is not possible to achieve this level of protection, the vaccine complies with the test if there is a significant reduction in morbidity and mortality of the vaccinated birds compared with the control birds.

3. BATCH TESTS

3-1. Identification

3-1-1. Identification of the vaccine virus. The vaccine, diluted if necessary and mixed with a monospecific Newcastle disease virus antiserum, no longer provokes haemagglutination of chicken red blood cells or infects embryonated hens' eggs from an SPF flock (5.2.2) or susceptible cell cultures (5.2.4) into which it is inoculated.

3-1-2. Identification of the virus strain. The strain of vaccine virus is identified by a suitable method, for example using monoclonal antibodies.

3-2. Bacteria and fungi

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. Mycoplasmas. The vaccine complies with the test for mycoplasmas (2.6.7).

3-4. Extraneous agents. The vaccine complies with the tests for extraneous agents in batches of finished product (2.6.25).

3-5. Safety. For vaccines recommended for use in chickens, use not fewer than 10 chickens from an SPF flock (5.2.2) and of the youngest age recommended for vaccination. For vaccines recommended for use only in avian species other than the chicken, use not fewer than 10 birds of the species likely to be most sensitive to Newcastle disease, that do not have antibodies against Newcastle disease virus and of the minimum age recommended for vaccination. Administer to each bird by eye-drop, or parenterally if only parenteral administration is recommended, 10 doses of the vaccine in a volume suitable for the test. Observe the birds at least daily for 21 days. The test is not valid if more than 20 per cent of the birds show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no bird shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. Virus titre. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (5.2.2) or into suitable cell cultures (5.2.4). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. Potency. Depending on the indications, the vaccine complies with 1 or both of the tests prescribed under Immunogenicity (section 2-4-5) when administered according to the recommended schedule by a recommended route and method. If the test in section 2-4-5-2. *Vaccine for use in avian species other than the chicken* is conducted and the vaccine is recommended for use in more than 1 avian species, the test is carried out with birds of that species for which the vaccine is recommended which is likely to be the most susceptible to avian paramyxovirus 1. It is not necessary

to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2005:2072

PASTEURELLA VACCINE (INACTIVATED) FOR SHEEP

Vaccinum pasteurellae inactivatum ad ovem

DEFINITION

Pasteurella vaccine (inactivated) for sheep is a preparation of one or more suitable strains of *Pasteurella trehalosi*. This monograph applies to vaccines intended for administration to sheep to protect against disease caused by *P. trehalosi*.

PRODUCTION

Production of the vaccine is based on a seed-lot system. The seed material is cultured in a suitable medium; each strain is cultivated separately and identity is verified using a suitable method. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity of the harvest are verified using suitable methods. After cultivation, the bacterial suspensions are collected separately and inactivated by a suitable method. The vaccine may contain an adjuvant and may be freeze-dried.

CHOICE OF VACCINE COMPOSITION

The choice of composition and the strains to be included in the vaccine is based on epidemiological data on the prevalence of the different serovars of *P. trehalosi*. The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) in sheep. As part of the studies to demonstrate the suitability of the vaccine with respect to these characteristics the following tests may be carried out.

Safety

- A. The test is carried out for each of the routes of administration to be stated on the label and in animals of each category (for example, young sheep, pregnant ewes) for which the vaccine is intended.

For each test, use not fewer than 10 animals that preferably do not have antibodies against the serovars of *P. trehalosi* or against leucotoxin present in the vaccine. Where justified, animals with a known history of no previous pasteurella vaccination and with low antibody titres (measured in a sensitive test system such as an ELISA) may be used.

Administer to each animal a double dose of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine. Administer a single dose of vaccine to each animal after the recommended interval. Observe the animals for at least 14 days after the last administration. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each animal. No abnormal local or systemic reaction occurs; the average body temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C. If the vaccine is intended for use or may be used in pregnant ewes, vaccinate the ewes at the relevant stages of pregnancy and prolong the observation period until 1 day after lambing.

The vaccine complies with the test if no animal shows abnormal local reactions or clinical signs of disease or dies from causes attributable to the vaccine. In addition, if the vaccine is intended for use in pregnant ewes, no significant effects on the pregnancy and offspring are demonstrated.

- B. The animals used for the field trials are also used to evaluate safety. Carry out a test in each category of animals for which the vaccine is intended. Use not fewer than 3 groups of 20 animals with corresponding groups of not fewer than 10 controls in 3 different locations. Examine the injection sites for local reactions after vaccination. Record body temperatures the day before vaccination, at vaccination and on the 2 days following vaccination. The vaccine complies with the test if no animal shows abnormal local or systemic reactions or clinical signs of disease or dies from causes attributable to the vaccine. The average body temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C. In addition, if the vaccine is intended for use in pregnant ewes, no significant effects on the pregnancy and offspring are demonstrated.

Immunogenicity. As part of the studies to demonstrate the suitability of the vaccine with respect to immunogenicity, the test described under Potency may be carried out for each proposed route of administration and using vaccine of minimum potency.

BATCH TESTING

Batch potency test. The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable validated batch potency test is carried out, the criteria for acceptance being set with reference to the results obtained with a batch of vaccine that has given satisfactory results in the test described under Potency.

Bacterial endotoxins. A test for bacterial endotoxins (2.6.14) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety test A given under Choice of vaccine composition or in the safety test described under Tests, carried out using 10 animals. Where the latter test is used, note the maximum temperature increase for each animal; the average body temperature increase for all animals does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for testing of each batch.

IDENTIFICATION

When injected into healthy seronegative animals, the vaccine stimulates the production of specific antibodies against the serovars of *P. trehalosi* and/or against the leucotoxin present in the vaccine.

TESTS

Safety. Use 2 sheep of the minimum age recommended for vaccination or, if not available, of an age as close as possible to the minimum recommended age, and that have not been vaccinated against Pasteurella. Administer a double dose of vaccine to each animal by a recommended route. Observe the animals for 14 days. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and

then daily for 2 days. The animals remain in good health and no abnormal local or systemic reaction occurs; a transient temperature increase not exceeding 2 °C may occur.

Sterility. It complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

POTENCY

Carry out a test for each serovar of *P. trehalosi* for which protection is claimed on the label.

Use not fewer than 20 lambs of the minimum age recommended for vaccination, free from antibodies against *P. trehalosi* and against the leucotoxin of *P. trehalosi*. Vaccinate not fewer than 10 of the animals by a recommended route and according to the recommended schedule. Keep 10 animals as controls. 21 days after the last vaccination, infect all the lambs by injection, using the subcutaneous or other suitable route, with a suitable quantity of a low-passage, virulent strain of a serovar of *P. trehalosi*. Observe the animals for a further 7 days; to avoid unnecessary suffering, severely ill animals are killed and are then considered to have died from the disease. During the observation period, the animals are examined for any signs of disease (for example, severe dullness, excess salivation) and the mortality is recorded. Kill surviving animals at the end of the observation period. Post-mortem examination is carried out on any animal that dies and those killed at the end of the observation period. The lungs, pleura, liver and spleen are examined for haemorrhages and the extent of lung consolidation due to pasteurellosis is evaluated. Samples of lung, liver and spleen tissue are collected for re-isolation of the challenge organisms. The mortality, clinical observations and the post-mortem lesions are scored and the results obtained for these parameters and the bacterial re-isolation results compared for the 2 groups.

The test is invalid if clinical signs or lesions of *P. trehalosi* infection occur in less than 70 per cent of the control lambs.

The vaccine complies with the requirements of the test if there is a significant difference between the scores obtained for the clinical and post-mortem observations in the vaccinates compared to the controls. For vaccines with a claim for a beneficial effect on the extent of infection against the serovar, the results for the infection rates are also significantly better for the vaccinates compared to the controls.

LABELLING

The label states:

- the serovar(s) of *P. trehalosi* against which protection is claimed,
- the serovar(s) of *P. trehalosi* and/or the leucotoxin present in the vaccine.

01/2005:1360

PORCINE ACTINOBACILLOSIS VACCINE (INACTIVATED)

Vaccinum actinobacillosis inactivatum
ad suem

DEFINITION

Porcine actinobacillosis vaccine (inactivated) is a liquid preparation which has one or more of the following components: inactivated *Actinobacillus pleuropneumoniae* of a suitable strain or strains; toxins, proteins or polysaccharides derived from suitable strains

of *A. pleuropneumoniae*, and treated to render them harmless; fractions of toxins derived from suitable strains of *A. pleuropneumoniae* and treated if necessary to render them harmless. This monograph applies to vaccines intended for protection of pigs against actinobacillosis.

PRODUCTION

The seed material is cultured in a suitable medium; each strain is cultivated separately. During production, various parameters such as growth rate, protein content and quantity of relevant antigens are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity are verified on the harvest using suitable methods. After cultivation, the bacterial suspensions are collected separately and inactivated by a suitable method. They may be detoxified, purified and concentrated. The vaccine may contain an adjuvant.

CHOICE OF VACCINE COMPOSITION

The choice of strains is based on epidemiological data. The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7) in pigs. The following tests may be used during demonstration of safety and immunogenicity.

Safety

- A. Carry out a test in each category of animals for which the vaccine is intended and by each of the recommended routes of administration. Use animals that do not have antibodies against the serotypes of *A. pleuropneumoniae* or its toxins present in the vaccine. Administer a double dose of vaccine by a recommended route to each of not fewer than 10 animals. Administer a single dose of vaccine to each of the animals after the interval recommended in the instructions for use. Observe the animals for 14 days after vaccination. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each animal. No abnormal local or systemic reaction occurs; the average temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C. If the vaccine is intended for use in pregnant sows, for the test in this category of animals, prolong the observation period up to farrowing and note any effects on gestation or the offspring.
- B. The animals used for field trials are also used to evaluate safety. Carry out a test in each category of animals for which the vaccine is intended. Use not fewer than 3 groups each of not fewer than 20 animals with corresponding groups of not fewer than 10 controls. Examine the injection site for local reactions after vaccination. Record body temperature the day before vaccination, at vaccination, at the time interval after which a rise in temperature, if any, was seen in test A, and daily during the 2 days following vaccination; note the maximum temperature increase for each animal. No abnormal local or systemic reaction occurs; the average temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C.

Immunogenicity. The test described under Potency may be used to demonstrate the immunogenicity of the vaccine.

BATCH TESTING

Batch potency test. The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given

satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Inject a suitable dose subcutaneously into each of 5 seronegative mice, weighing 18-20 g. Where the schedule stated on the label requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. Before the vaccination and at a given interval within the range of 14-21 days after the last injection, collect blood from each animal and prepare serum samples. Determine individually for each serum the titre of specific antibodies against each antigenic component stated on the label, using a suitable validated test such as enzyme-linked immunosorbent assay (2.7.1). The vaccine complies with the test if the antibody levels are not significantly lower than those obtained for a batch that has given satisfactory results in the test described under Potency.

Bacterial endotoxins. A test for bacterial endotoxins (2.6.14) is carried out on the final bulk or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety test A described under Choice of vaccine composition or the safety test described under Tests, carried out using 10 pigs. Where the latter test is used, note the maximum temperature increase for each animal; the average temperature increase for all animals does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for batch testing.

IDENTIFICATION

When injected into healthy seronegative animals, the vaccine stimulates the production of specific antibodies against the antigenic components of *A. pleuropneumoniae* stated on the label.

TESTS

Safety. Use 2 pigs of the minimum age stated for vaccination and which do not have antibodies against the serotypes of *A. pleuropneumoniae* or its toxins present in the vaccine. Administer to each pig a double dose of vaccine by a recommended route. Observe the animals for 14 days. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days. No abnormal local or systemic reaction occurs; a transient temperature increase not exceeding 2 °C may occur.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

The challenge strain for the potency test is chosen to ensure challenge with each Ap toxin ⁽¹⁾ produced by the serotypes stated on the label; it may be necessary to carry out more than one test using a different challenge strain for each test.

Vaccinate according to the recommended schedule not fewer than 7 pigs, of the minimum age recommended for vaccination, which do not have antibodies against *A. pleuropneumoniae* and Ap toxins. Keep not fewer than 7 unvaccinated pigs of the same age as controls. 3 weeks after the last vaccination, challenge all the pigs intranasally

or intratracheally or by aerosol with a suitable quantity of a serotype of *A. pleuropneumoniae*. Observe the animals for 7 days; to avoid unnecessary suffering, severely ill control animals are killed and are then considered to have died from the disease. Kill all surviving animals at the end of the observation period. Carry out a post-mortem examination on all animals. Examine the lungs, the tracheobronchial lymph nodes and the tonsils for the presence of *A. pleuropneumoniae*. Evaluate the extent of lung lesions at post-mortem examination. Each of the 7 lobes of the lungs is allotted a maximum possible lesion score ⁽²⁾ of 5. The area showing pneumonia and/or pleuritis of each lobe is assessed and expressed on a scale of 0 to 5 to give the pneumonic score per lobe (the maximum total score possible for each complete lung is 35). Calculate separately for the vaccinated and the control animals the total score (the maximum score per group is 245, if 7 pigs are used per group).

The vaccine complies with the test if the vaccinated animals, when compared with controls, show lower incidence of: mortality; typical clinical signs (dyspnoea, coughing and vomiting); typical lung lesions; re-isolation of *A. pleuropneumoniae* from the lungs, the tracheobronchial lymph nodes and the tonsils. Where possible, the incidence is analysed statistically and shown to be significantly lower for vaccinates.

LABELLING

The label states:

- the antigens present in the vaccine,
- the serotypes of *A. pleuropneumoniae* for which the vaccine affords protection.

01/2005:0963

PORCINE INFLUENZA VACCINE (INACTIVATED)

Vaccinum influenzae inactivatum ad suem

DEFINITION

Porcine influenza vaccine (inactivated) is an aqueous suspension, an oily emulsion or a freeze-dried preparation of one or more inactivated strains of swine or human influenza virus. Suitable strains contain both haemagglutinin and neuraminidase.

PRODUCTION

The virus is propagated in the allantoic cavity of fertilised hen eggs from a healthy flock or in suitable cell cultures (5.2.4). Each virus strain is cultivated separately. After cultivation, the viral suspensions are collected separately and inactivated by a method that avoids destruction of the immunogenicity. If necessary, they may be purified.

An amplification test for residual infectious influenza virus is carried out on each batch of antigen immediately after inactivation by passage in the same type of substrate as that used for production (eggs or cell cultures) or a substrate shown to be at least as sensitive. The quantity of inactivated virus used in the test is equivalent to not less than 10 doses of the vaccine. No live virus is detected.

The vaccine may contain one or more suitable adjuvants; it may be freeze-dried.

(1) The nomenclature of the toxins of *A. pleuropneumoniae* is described by J. Frey *et al.*, *Journal of General Microbiology*, 1993, 139, 1723-1728.

(2) The system of lung scores is described in detail by P.C.T. Hannan, B.S. Bhogal, J.P. Fish, *Research in Veterinary Science*, 1982, 33, 76-88.

CHOICE OF VACCINE COMPOSITION

The choice of strains is based on the antigenic types and sub-types observed in Europe. The vaccine is shown to be satisfactory with respect to safety and immunogenicity for pigs. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Safety

- A. A test is carried out in each category of animal for which the vaccine is intended (sows, fattening pigs). The animals used do not have antibodies against swine influenza virus. 2 doses of vaccine are injected by the intended route into each of not fewer than 10 animals. After 14 days, 1 dose of vaccine is injected into each of the animals. The animals are observed for a further 14 days. During the 28 days of the test, no abnormal local or systemic reaction is produced.
- B. The animals used in the test for immunogenicity are also used to evaluate safety. The rectal temperature of each vaccinated animal is measured at the time of vaccination and 24 h and 48 h later. No abnormal effect on rectal temperature is noted nor other systemic reactions (for example, anorexia). The injection site is examined for local reactions at slaughter. No abnormal local reaction occurs.
- C. The animals used for field trials are also used to evaluate safety. A test is carried out in each category of animals for which the vaccine is intended (sows, fattening pigs). Not fewer than 3 groups each of not fewer than 20 animals in at least 2 locations are used with corresponding groups of not fewer than 10 controls. The rectal temperature of each animal is measured at the time of vaccination and 24 h and 48 h later. No abnormal effect on rectal temperature is noted. The injection site is examined for local reactions at slaughter. No abnormal local reaction occurs.

Immunogenicity. The test described under Potency carried out using an epidemiologically relevant challenge strain or strains is suitable to demonstrate the immunogenicity of the vaccine.

IN-PROCESS TESTS

For vaccines produced in eggs, the content of bacterial endotoxins is determined on the virus harvest to monitor production.

BATCH POTENCY TEST

The test described below under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established by a statistical evaluation.

Inject subcutaneously into each of 5 seronegative guinea-pigs, 5 to 7 weeks old, a quarter of the dose stated on the label. Collect blood samples before the vaccination and 21 days after vaccination. Determine for each sample the level of specific antibodies against each virus subtype in the vaccine by haemagglutination-inhibition or another suitable test. The vaccine complies with the test if the level of antibodies is not lower than that found for a batch of vaccine that gave satisfactory results in the potency test in pigs (see Potency).

IDENTIFICATION

When injected into healthy, susceptible animals, the vaccine stimulates the production of specific antibodies against the influenza virus subtypes included in the vaccine. The antibodies may be detected by a suitable immunochemical method (2.7.1).

TESTS

Safety. Use 2 pigs, free from antibodies against swine influenza virus and not older than the minimum age stated for vaccination. Inject into each pig a double dose of vaccine by the route stated on the label. Observe the animals for 14 days and then inject into each animal 1 dose of vaccine. Observe the animals for 14 days. No abnormal local or systemic reaction occurs during the 28 days of the test.

Inactivation. If the vaccine has been prepared in eggs, inoculate 0.2 ml into the allantoic cavity of each of 10 fertilised hen eggs, 9 to 11 days old. Incubate at a suitable temperature for 3 days. The death of any embryo within 24 h of inoculation is considered as non-specific mortality and the egg is discarded. The test is not valid unless at least 80 per cent of the eggs survive. Collect the allantoic fluid of each egg, pool equal quantities and carry out a second passage on fertilised eggs in the same manner. Incubate for 4 days; the allantoic fluid of these eggs shows no haemagglutinating activity.

If the vaccine has been prepared in cell cultures, carry out a suitable test for residual infectious influenza virus using 2 passages in the same type of cell culture as used in the production of vaccine. No live virus is detected. If the vaccine contains an oily adjuvant that interferes with this test, where possible separate the aqueous phase from the vaccine by means that do not diminish the capacity to detect residual infectious influenza virus.

Extraneous viruses. On the pigs used for the safety test, carry out tests for antibodies. The vaccine does not stimulate the formation of antibodies other than those against influenza virus. In particular, no antibodies against viruses pathogenic for pigs or against viruses which could interfere with the diagnosis of infectious diseases of pigs (including viruses of the pestivirus group) are detected.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Carry out a potency test for each subtype used in the preparation of the vaccine. Use not fewer than 20 pigs of the minimum age recommended for vaccination and that do not have antibodies against swine influenza virus. Vaccinate not fewer than 10 pigs as recommended on the label and keep not fewer than 10 pigs as unvaccinated controls. Take a blood sample from all control pigs immediately before challenge. 3 weeks after the last administration of vaccine, challenge all the pigs with a suitable quantity of a virulent influenza field virus by the intratracheal route. Kill half of the vaccinated and control pigs 24 h after challenge and the other half 72 h after challenge. For each pig, measure the quantity of influenza virus in 2 lung tissue homogenates, one from the left apical, cardiac and diaphragmatic lobes, and the other from the corresponding right lung lobes. Take equivalent samples from each animal. The test is invalid if antibodies against influenza virus are found in any control pig immediately before challenge. The vaccine complies with the test if, at both times of measurement, the mean virus titre in the pooled lung tissue samples of vaccinated pigs is

significantly lower than that for control pigs, when analysed by a suitable statistical method such as the Wilcoxon Mann-Whitney test.

01/2005:0965

PORCINE PARVOVIROSIS VACCINE (INACTIVATED)

Vaccinum parvovirus inactivatum ad suem

DEFINITION

Inactivated porcine parvovirus vaccine consists of a suspension of inactivated porcine parvovirus or of a noninfectious fraction of the virus.

PRODUCTION

The virus is grown in suitable cell cultures (5.2.4). The viral suspension is harvested; the virus is inactivated by a method that avoids destruction of the immunogenicity and may be fragmented (inactivation may be by fragmentation); the virus or viral fragments may be purified and concentrated at a suitable stage of the process.

A test for residual infectious porcine parvovirus is carried out on each batch of antigen immediately after inactivation and on the final bulk or, if the vaccine contains an adjuvant, on the bulk antigen or the mixture of bulk antigens immediately before the addition of adjuvant. The quantity used in the test is equivalent to not less than 100 doses of the vaccine. The bulk harvest is inoculated into suitable non-confluent cells; after incubation for 7 days, a subculture is made using trypsinised cells. After incubation for a further 7 days, the cultures are examined for residual live parvovirus by an immunofluorescence test. No live virus is detected.

The vaccine may contain one or more suitable adjuvants.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (including absence of adverse effects on fertility, gestation, farrowing or offspring) and immunogenicity in pigs. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

Safety

- A. A test is carried out in each category of animals for which the vaccine is intended and by each of the recommended routes. The animals used do not have antibodies against porcine parvovirus or against a fraction of the virus. Two doses of vaccine are injected by the intended route into each of not fewer than ten animals. After 14 days, one dose of vaccine is injected into each of the animals. The animals are observed for a further 14 days. During the 28 days of the test, no abnormal local or systemic reaction occurs. If the vaccine is intended for use in pregnant sows, for the test in this category of animal, the observation period is prolonged up to farrowing and any effects on gestation or the offspring are noted.
- B. The animals used in the test for immunogenicity are also used to evaluate safety. The rectal temperature of each vaccinated animal is measured at the time of vaccination and 24 h and 48 h later. No abnormal effect on body temperature is noted nor other systemic reactions (for example, anorexia). The injection site is examined for local reactions after vaccination and at slaughter. No abnormal local reaction occurs.
- C. The animals used for field trials are also used to evaluate safety. A test is carried out in each category of animals for which the vaccine is intended (sows, gilts). Not fewer

than three groups each of not fewer than twenty animals are used with corresponding groups of not fewer than ten controls. The rectal temperature of each animal is measured at the time of vaccination and 24 h and 48 h later. No abnormal effect on body temperature is noted. The injection site is examined for local reactions after vaccination and at slaughter. No abnormal local reaction occurs.

Immunogenicity. The test described under Potency may be used to demonstrate the immunogenicity of the vaccine.

BATCH POTENCY TEST

The test described below is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established by a statistical evaluation.

Vaccinate subcutaneously not fewer than five guinea-pigs, 5 to 7 weeks old, according to the vaccination scheme stated on the label using one-fourth of the prescribed dose volume. Take blood samples after the period corresponding to maximum antibody production and carry out tests on the serum for specific antibodies by a haemagglutination-inhibition test or other suitable test. The antibody titres are not less than those obtained with a batch of vaccine shown to be satisfactory in the test in pigs (see Potency).

IDENTIFICATION

The vaccine stimulates the formation of specific antibodies against porcine parvovirus or the fraction of the virus used in the production of the vaccine when injected into susceptible animals on one or, if necessary, more than one occasion.

TESTS

Safety. Use two pigs 6 weeks to 6 months old and having no antibodies against porcine parvovirus virus or against a fraction of the virus. Inject into each animal by one of the routes stated on the label a double dose of vaccine. Observe the animals for 14 days and then inject a single dose of vaccine into each pig. Observe the animals for a further 14 days. No abnormal local or systemic reaction occurs during the 28 days of the test.

Inactivation. *This test may be omitted by the manufacturer if a test for inactivation has been carried out on the bulk vaccine, immediately before the addition of the adjuvant, where applicable.* Use a quantity of vaccine equivalent to ten doses. If the vaccine contains an oily adjuvant, break the emulsion and separate the phases. If the vaccine contains a mineral adjuvant, carry out an elution to liberate the virus. Concentrate the viral suspension 100 times by ultrafiltration or ultracentrifugation. None of the above procedures must be such as to inactivate or otherwise interfere with detection of live virus. Carry out a test for residual live virus in suitable non-confluent cells; after incubation for 7 days, make a subculture using trypsinised cells. After incubation for a further 7 days, examine the cultures for residual live parvovirus by an immunofluorescence test. No live virus is detected.

Extraneous viruses. On the pigs used for the safety test carry out tests for antibodies. The vaccine does not stimulate the formation of antibodies - other than those against porcine parvovirus - against viruses pathogenic for pigs or

against viruses which could interfere with the diagnosis of infectious diseases in pigs (including the viruses of the pestivirus group).

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Vaccinate according to the recommended schedule not less than seven gilts, 5 to 6 months old, which do not have antibodies against porcine parvovirus or against a fraction of the virus. The interval between vaccination and service is that stated on the label. Mate the gilts on two consecutive days immediately following signs of oestrus. Keep not less than five unvaccinated mated gilts of the same age as controls. At about the 40th day of gestation, challenge all gilts using a suitable strain of porcine parvovirus. Slaughter the gilts at about the 90th day of gestation and examine their foetuses for infection with porcine parvovirus as demonstrated by the presence of either virus or antibodies. The vaccine complies with the test if not fewer than 80 per cent of the total number of piglets from vaccinated gilts are protected from infection. The test is not valid unless: not fewer than seven vaccinated gilts and five control gilts are challenged; not fewer than 90 per cent of piglets from the control gilts are infected; and the average number of piglets per litter for the vaccinated gilts is not less than six.

01/2005:1361

PORCINE PROGRESSIVE ATROPHIC RHINITIS VACCINE (INACTIVATED)

*Vaccinum rhinitidis atrophicantis
ingravescentis suillae inactivatum*

DEFINITION

Porcine progressive atrophic rhinitis vaccine (inactivated) is a preparation containing either the dermonecrotic exotoxin of *Pasteurella multocida*, treated to render it harmless while maintaining adequate immunogenic activity, or a genetically modified form of the exotoxin which has adequate immunogenic activity and which is free from toxic properties; the vaccine may also contain cells and/or antigenic components of one or more suitable strains of *P. multocida* and/or *Bordetella bronchiseptica*. This monograph applies to vaccines administered to sows and gilts for protection of their progeny.

PRODUCTION

The bacterial strains used for production are cultured separately in suitable media. The toxins and/or cells are treated to render them safe.

Detoxification. A test for detoxification of the dermonecrotic exotoxin of *P. multocida* is carried out immediately after detoxification. The concentration of detoxified exotoxin used in the test is not less than that in the vaccine. The suspension complies with the test if no toxic dermonecrotic exotoxin is detected. The test for detoxification is not required where the vaccine is prepared using a toxin-like protein free from toxic properties, produced by expression of a modified form of the corresponding gene.

Antigen content. The content of the dermonecrotic exotoxin of *P. multocida* in the detoxified suspension or the toxin-like protein in the harvest is determined by a suitable immunochemical method (2.7.1), such as an enzyme-linked

immunosorbent assay and the value found is used in the formulation of the vaccine. The content of other antigens stated on the label is also determined (2.7.1).

The vaccine may contain a suitable adjuvant.

CHOICE OF VACCINE COMPOSITION

The strains used for the preparation of the vaccine are shown to be satisfactory with respect to the production of the dermonecrotic exotoxin and the other antigens claimed to be protective. The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7).

Production of antigens. The production of antigens claimed to be protective is verified by a suitable bioassay or immunochemical method (2.7.1), carried out on the antigens obtained from each of the vaccine strains under the conditions used for the production of the vaccine.

The following tests may be used during demonstration of safety and immunogenicity.

Safety

- A. Carry out the test for each route of administration stated on the label. Use pigs that do not have antibodies against the components of the vaccine, that are from a herd or herds where there are no signs of atrophic rhinitis and that have not been vaccinated against atrophic rhinitis. If the vaccine is intended for use in pregnant animals, carry out the test in pregnant sows or gilts, vaccinating them at the recommended stage of pregnancy. Administer a double dose of vaccine by a recommended route to each of not fewer than 10 sows or gilts. Administer a single dose of vaccine to each of the animals after the recommended interval. Observe the pigs until farrowing. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each animal. Note any effects on gestation and the offspring. No abnormal local or systemic reaction occurs; the average temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C.
- B. The animals used for field trials are also used to evaluate safety. Use not fewer than 3 groups each of not fewer than 20 animals with corresponding groups of not fewer than 10 controls. Examine the injection site for local reactions after vaccination. Record body temperature the day before vaccination, at vaccination, at the time interval after which a rise in temperature, if any, was seen in test A, and daily during the 2 days following vaccination; note the maximum temperature increase for each animal. No abnormal local or systemic reaction occurs; the average temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C.

Immunogenicity. The test described under Potency is suitable for demonstration of immunogenicity.

BATCH TESTING

Batch potency test. The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established. Use not fewer than 5 pigs not less than 3 weeks old and that do not have antibodies against the components of the vaccine. Vaccinate each pig by a recommended route and according to the recommended schedule. Maintain not fewer

than 2 pigs of the same origin as unvaccinated controls under the same conditions.

Alternatively, if the nature of the antigens allows reproducible results to be obtained, a test in susceptible laboratory animals may be carried out. To obtain a valid assay, it may be necessary to carry out a test using several groups of animals, each receiving a different quantity of vaccine. For each quantity of vaccine, carry out the test as follows: vaccinate not fewer than 5 animals with a suitable quantity of vaccine. Maintain not fewer than 2 animals of the same species and origin as unvaccinated controls. Where the schedule stated on the label requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval within the range of 14 to 21 days after the last administration, collect blood from each animal and prepare serum samples. Use a validated test such as an enzyme-linked immunosorbent assay to measure the antibody response to each of the antigens stated on the label. The test is not valid and must be repeated if there is a significant antibody titre in the controls. The vaccine complies with the test if the antibody responses of the vaccinated animals are not significantly less than those obtained with a batch of vaccine that has given satisfactory results in the test or tests (as applicable) described under Potency.

Where animals seronegative for the antigens stated on the label are not available, seropositive animals may be used in the above test. During the development of a test with seropositive animals, particular care will be required during the validation of the test system to establish that the test is suitably sensitive and to specify acceptable pass, fail and retest criteria. It will be necessary to take into account the range of prevaccination antibody titres and to establish the acceptable minimum antibody titre rise after vaccination in relation to these.

Bacterial endotoxins. A test for bacterial endotoxins (2.6.14) is carried out on the batch or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine shown satisfactory in safety test A given under Choice of vaccine composition or in the safety test described under Tests, carried out using 10 pigs. Where the latter test is used, note the maximum temperature increase for each animal; the average temperature increase for all animals does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for testing of each batch.

IDENTIFICATION

In animals free from specific antibodies against the antigens stated on the label, the vaccine stimulates the production of antibodies against these antigens.

TESTS

Safety. Use not fewer than 2 pigs that do not have antibodies against *P. multocida* and that preferably do not have antibodies against *B. bronchiseptica*. Administer to each pig a double dose of vaccine by a recommended route. Observe the pigs for 14 days. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days. No abnormal local or systemic reaction occurs; a transient temperature increase not exceeding 2 °C may occur.

Sterility (2.6.1). The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

POTENCY

Use pigs that do not have antibodies against the components of the vaccine, that are from a herd or herds where there are no signs of atrophic rhinitis and that have not been vaccinated against atrophic rhinitis.

A. Vaccines containing dermonecrotic exotoxin of *P. multocida* (with or without cells of *P. multocida*).

Use not fewer than 12 breeder pigs. Vaccinate not fewer than 6 randomly chosen pigs at the stage of pregnancy or non-pregnancy and by the route and schedule stated on the label. Maintain not fewer than 6 of the remaining pigs as unvaccinated controls under the same conditions. From birth allow all the piglets from the vaccinated and unvaccinated breeder pigs to feed from their own dam.

Constitute from the progeny 2 challenge groups each of not fewer than 30 piglets chosen randomly, taking not fewer than 3 piglets from each litter. On the 2 consecutive days preceding challenge, the mucosa of the nasal cavity of the piglets may be treated by instillation of 0.5 ml of a solution of acetic acid (10 g/l C₂H₄O₂) in isotonic buffered saline pH 7.2.

Challenge each piglet at 10 days of age by the intranasal route with a sufficient quantity of a toxigenic strain of *P. multocida*.

At the age of 42 days, kill the piglets of the 2 groups and dissect the nose of each of them transversally at premolar-1. Examine the ventral and dorsal turbinates and the nasal septum for evidence of atrophy or distortion and grade the observations on the following scales:

Turbinates

- | | |
|---|---|
| 0 | no atrophy |
| 1 | slight atrophy |
| 2 | moderate atrophy |
| 3 | severe atrophy |
| 4 | very severe atrophy with almost complete disappearance of the turbinate |

The maximum score is 4 for each turbinate and 16 for the sum of the 2 dorsal and 2 ventral turbinates.

Nasal septum

- | | |
|---|-------------------------|
| 0 | no deviation |
| 1 | very slight deviation |
| 2 | deviation of the septum |

The maximum total score for the turbinates and the nasal septum is 18.

The test is not valid and must be repeated if fewer than 80 per cent of the progeny of each litter of the unvaccinated breeder pigs have a total score of at least 10. The vaccine complies with the test if a significant reduction in the total score has been demonstrated in the group from the vaccinated breeder pigs compared to that from the unvaccinated breeder pigs.

B. Vaccines containing *P. multocida* dermonecrotic exotoxin (with or without cells of *P. multocida*) and cells and/or antigenic components of *B. bronchiseptica*.

Use not fewer than 24 breeder pigs. Vaccinate not fewer than 12 randomly chosen pigs at the stage of pregnancy or non-pregnancy and by the route and schedule stated on the label. Maintain not fewer than 12 of the remaining

pigs as unvaccinated controls under the same conditions. From birth allow all the piglets from the vaccinated and unvaccinated breeder pigs to feed from their own dam.

Using groups of not fewer than 6 pigs, constitute from their progeny 2 challenge groups from vaccinated pigs and 2 groups from unvaccinated pigs each group consisting of not fewer than 30 piglets chosen randomly, taking not fewer than 3 piglets from each litter. On the 2 consecutive days preceding challenge, the mucosa of the nasal cavity of the piglets may be treated by instillation of 0.5 ml of a solution of acetic acid (10 g/l C₂H₄O₂) in isotonic buffered saline pH 7.2.

For a group of piglets from not fewer than 6 vaccinated pigs and a group from not fewer than 6 controls, challenge each piglet by the intranasal route at 10 days of age with a sufficient quantity of a toxigenic strain of *P. multocida*.

For the other group of piglets from not fewer than 6 vaccinated pigs and the other group from not fewer than 6 controls, challenge each piglet at 7 days of age by the intranasal route with a sufficient quantity of *B. bronchiseptica*. In addition, challenge each piglet at 10 days of age by the intranasal route with a sufficient quantity of a toxigenic strain of *P. multocida*.

At the age of 42 days, kill the piglets of the 4 groups and dissect the nose of each of them transversally at premolar-1. Examine the ventral and dorsal turbinates and the nasal septum for evidence of atrophy or distortion and grade the observations on the scale described above.

The test is not valid and must be repeated if fewer than 80 per cent of the progeny of each litter of the unvaccinated breeder pigs have a total score of at least 10. The vaccine complies with the test if a significant reduction in the total score has been demonstrated in the groups from the vaccinated breeder pigs compared to the corresponding group from the unvaccinated breeder pigs.

LABELLING

The label states the protective antigens present in the vaccine.

01/2005:0451

RABIES VACCINE (INACTIVATED) FOR VETERINARY USE

*Vaccinum rabiei inactivatum
ad usum veterinarium*

DEFINITION

Rabies vaccine (inactivated) for veterinary use is a liquid or freeze-dried preparation of fixed rabies virus inactivated by a suitable method.

PRODUCTION

The vaccine is prepared from virus grown either in suitable cell lines or in primary cell cultures from healthy animals (5.2.4). The virus suspension is harvested on one or more occasions within 28 days of inoculation. Multiple harvests from a single production cell culture may be pooled and considered as a single harvest. The rabies virus is inactivated by a suitable method.

Inactivation. The test for residual live rabies virus is carried out by inoculation of the inactivated virus into the same type of cell culture as that used in the production of the vaccine or a cell culture shown to be at least as sensitive; the quantity of inactivated virus used in the test is equivalent to not less than 25 doses of the vaccine. After incubation for

4 days, a subculture is made using trypsinised cells; after incubation for a further 4 days, the cultures are examined for residual live rabies virus by an immunofluorescence test. No live virus is detected.

Antigen content. The content of rabies virus glycoprotein is determined by a suitable immunochemical method (2.7.1). The content is within the limits approved for the particular preparation.

The vaccine may contain one or more adjuvants.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to immunogenicity for each species for which it is recommended. The suitability of the vaccine with respect to immunogenicity for carnivores (cats and dogs) is demonstrated by direct challenge. For other species, if a challenge test has been carried out for the vaccine in cats or dogs, an indirect test is carried out by determining the antibody level following vaccination of not fewer than twenty animals according to the recommended schedule; the vaccine is satisfactory if, after the period claimed for protection, the mean rabies virus antibody level in the serum of the animals is not less than 0.5 IU/ml and if not more than 10 per cent of the animals have an antibody level less than 0.1 IU/ml. The test described below may be used to demonstrate immunogenicity in cats and dogs.

Immunogenicity. Use not fewer than 35 susceptible animals of the minimum age recommended for vaccination. Take a blood sample from each animal and test individually for antibodies against rabies virus to determine susceptibility. Administer by the recommended route to each of not fewer than 25 animals one dose of vaccine. Keep not fewer than 10 animals as controls. Observe all the animals for a period equal to the claimed duration of immunity. No animal shows signs of rabies. On the last day of the claimed period for duration of immunity or later, challenge all animals by intramuscular injection of virulent rabies virus of a strain approved by the competent authority. Observe the animals for 90 days. Animals that die from causes not attributable to rabies are eliminated. The test is not valid if the number of such deaths reduces the number of vaccinated animals in the test to fewer than 25. The test is not valid unless at least eight control animals (or a statistically equivalent number if more than 10 control animals are challenged) show signs of rabies and the presence of rabies virus in their brain is demonstrated by the fluorescent-antibody test or some other suitable method. The vaccine complies with the test if not more than 2 of the 25 vaccinated animals (or a statistically equivalent number if more than 25 vaccinated animals are challenged) show signs of rabies.

BATCH TESTING

The test described under Potency is not necessarily carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority; where the test is not carried out, a suitable validated alternative method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described above for immunogenicity or in the test described under Potency. The following test may be used after a suitable correlation with the test described above for immunogenicity or the test described under Potency has been established.

Batch potency test. Use 5 mice each weighing 18 g to 20 g. Vaccinate each mouse subcutaneously or intramuscularly using one-fifth of the recommended dose volume. Take blood samples 14 days after the injection and test the sera individually for rabies antibody using the rapid

fluorescent focus inhibition test described for *Human rabies immunoglobulin* (0723). The amount of antibody is not less than that produced by a vaccine that has been found satisfactory with respect to immunogenicity as described above or in the test described under Potency.

Antigen content. The quantity of rabies virus glycoprotein per dose, determined by a suitable immunochemical method (2.7.1), is not significantly lower than that of a batch that has been found satisfactory with respect to immunogenicity as described above or in the test described under Potency.

IDENTIFICATION

When injected into animals, the vaccine stimulates the production of specific neutralising antibodies.

TESTS

Safety. If the vaccine is intended for more than one species including one belonging to the order of Carnivora, carry out the test in dogs. Otherwise use one of the species for which the vaccine is intended. Administer, by a recommended route, a double dose of vaccine to each of 2 animals having no antibodies against rabies virus. Observe the animals for 14 days. No abnormal local or systemic reaction occurs.

Inactivation. Carry out the test using a pool of the contents of 5 containers.

For vaccines which do not contain an adjuvant, carry out a suitable amplification test for residual infectious rabies virus using the same type of cell culture as that used in the production of the vaccine or a cell culture shown to be at least as sensitive. No live virus is detected.

For vaccines that contain an adjuvant, inject intracerebrally into each of not fewer than 10 mice each weighing 11 g to 15 g 0.03 ml of a pool of at least 5 times the smallest stated dose. To avoid interference from any antimicrobial preservative or the adjuvant, the vaccine may be diluted not more than 10 times before injection. In this case or if the vaccine strain is pathogenic only for unweaned mice, carry out the test on mice 1 to 4 days old. Observe the animals for 21 days. If more than 2 animals die during the first 48 h, repeat the test. From the third to the twenty-first days following the injection, the animals show no signs of rabies and immunofluorescence tests carried out on the brains of the animals show no indication of the presence of rabies virus.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

The potency of rabies vaccine is determined by comparing the dose necessary to protect mice against the clinical effects of the dose of rabies virus defined below, administered intracerebrally, with the quantity of a reference preparation, calibrated in International Units, necessary to provide the same protection.

The International Unit is the activity of a stated quantity of the International Standard. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Rabies vaccine (inactivated) for veterinary use BRP is calibrated in International Units against the International Standard.

The test described below uses a parallel-line model with at least 3 points for the vaccine to be examined and the reference preparation. Once the analyst has experience with the method for a given vaccine, it is possible to carry

out a simplified test using one dilution of the vaccine to be examined. Such a test enables the analyst to determine that the vaccine has a potency significantly higher than the required minimum but will not give full information on the validity of each individual potency determination. It allows a considerable reduction in the number of animals required for the test and should be considered by each laboratory in accordance with the provisions of the European Convention for the Protection of Vertebrate Animals used for Experimental and other Scientific Purposes.

Selection and distribution of the test animals. Use in the test healthy female mice about 4 weeks old and from the same stock. Distribute the mice into at least 10 groups of not fewer than 10 mice.

Preparation of the challenge suspension. Inoculate a group of mice intracerebrally with the CVS strain of rabies virus and when the mice show signs of rabies, but before they die, kill the mice and remove the brains and prepare a homogenate of the brain tissue in a suitable diluent. Separate gross particulate matter by centrifugation and use the supernatant liquid as challenge suspension. Distribute the suspension in small volumes in ampoules, seal and store at a temperature below -60°C . Thaw one ampoule of the suspension and make serial dilutions in a suitable diluent. Allocate each dilution to a group of mice and inject intracerebrally into each mouse 0.03 ml of the dilution allocated to its group. Observe the animals for 14 days and record the number in each group that, between the fifth and the fourteenth days, develop signs of rabies. Calculate the ID_{50} of the undiluted suspension.

Determination of potency of the vaccine to be examined. Prepare at least three serial dilutions of the vaccine to be examined and three similar dilutions of the reference preparation. Prepare the dilutions such that those containing the largest quantity of vaccine may be expected to protect more than 50 per cent of the animals into which they are injected and those containing the smallest quantities of vaccine may be expected to protect less than 50 per cent of the animals into which they are injected. Allocate each dilution to a different group of mice and inject intraperitoneally into each mouse 0.5 ml of the dilution allocated to its group. 14 days after the injection prepare a suspension of the challenge virus such that, on the basis of the preliminary titration, it contains about 50 ID_{50} in each 0.03 ml. Inject intracerebrally into each vaccinated mouse 0.03 ml of this suspension. Prepare 3 suitable serial dilutions of the challenge suspension. Allocate the challenge suspension and the 3 dilutions one to each of 4 groups of 10 unvaccinated mice and inject intracerebrally into each mouse 0.03 ml of the suspension or one of the dilutions allocated to its group. Observe the animals in each group for 14 days. The test is not valid if more than 2 mice of any group die within the first 4 days after challenge. Record the numbers in each group that show signs of rabies in the period 5 days to 14 days after challenge.

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation the 50 per cent protective dose lies between the smallest and the largest dose given to the mice,
- the titration of the challenge suspension shows that 0.03 ml of the suspension contained at least 10 ID_{50} ,
- the confidence limits ($P = 0.95$) are not less than 25 per cent and not more than 400 per cent of the estimated potency,
- the statistical analysis shows a significant slope and no significant deviations from linearity or parallelism of the dose-response lines.

The vaccine complies with the test if the estimated potency is not less than 1 IU in the smallest prescribed dose.

LABELLING

The label states:

- the type of cell culture used to prepare the vaccine and the species of origin,
- the minimum number of International Units per dose,
- the minimum period for which the vaccine provides protection.

01/2005:0746

RABIES VACCINE (LIVE, ORAL) FOR FOXES

Vaccinum rabiei perorale vivum ad vulpem

DEFINITION

Rabies vaccine (live, oral) for foxes is a preparation of an immunogenic strain of an attenuated rabies virus. The vaccine is incorporated in a bait in such a manner as to enable the tests prescribed below to be performed aseptically.

PRODUCTION

The attenuated virus strain is grown in suitable cell cultures (5.2.4); if the cell cultures are of mammalian origin, they are shown to be free from rabies virus. The virus suspension is harvested on one or more occasions within 14 days of inoculation. Multiple harvests from a single cell lot may be pooled and considered as a single harvest. The viral suspension may be mixed with a suitable stabiliser. The vaccine may be freeze-dried or liquid. A freeze-dried vaccine has to be reconstituted before use.

CHOICE OF VACCINE STRAIN

Only a virus strain shown to be satisfactory with respect to immunogenicity (see Potency) and the following characteristics may be used in the preparation of the vaccine:

- when administered orally at the dose and by the method recommended for use to forty foxes, it causes no sign of rabies within 180 days of administration,
- when administered orally at ten times the recommended dose to each of ten foxes, it causes no sign of rabies within 180 days of administration,
- when administered orally at ten times the recommended dose to each of ten dogs, it causes no sign of rabies within 180 days of administration,
- when administered orally at ten times the recommended dose to each of ten cats, it causes no sign of rabies within 180 days of administration,
- in natural and experimental conditions, the virus strain does not spread from one animal to another in wild rodents,
- the virus strain has one or more stable genetic markers that may be used to discriminate the vaccine strain from other rabies virus strains.

BATCH TESTING

If the test for potency has been carried out with satisfactory results on a representative batch of vaccine, this test may be omitted as a routine control on other batches of vaccine prepared from the same seed lot.

IDENTIFICATION

- When mixed with a monospecific rabies antiserum, the vaccine is no longer able to infect susceptible cell cultures into which it is inoculated.
- A test is carried out to demonstrate the presence of the genetic marker.

TESTS

Extraneous viruses

(a) Mix the vaccine with a specific neutralising rabies virus antiserum. It no longer provokes cytopathic effects in susceptible cell cultures. It shows no evidence of haemagglutinating or haemadsorbing agents.

(b) Inoculate 1 in 10 and 1 in 1000 dilutions of the vaccine into susceptible cell cultures. Incubate at 37 °C. After 2, 4 and 6 days, stain the cells with a panel of monoclonal antibodies that do not react with the vaccine strain but that react with other strains of rabies virus (for example, street virus, Pasteur strain). The vaccine shows no evidence of contaminating rabies virus.

Bacterial and fungal contamination. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

Mycoplasmas (2.6.7). The vaccine complies with the test for mycoplasmas.

Virus titre. Titrate the vaccine in suitable cell cultures. One dose of the vaccine contains not less than the quantity of virus equivalent to the minimum titre stated on the label.

POTENCY

Use not fewer than thirty-five foxes, at least three months old, free from rabies-neutralising antibodies. Administer orally and with the bait stated on the label to each of not fewer than twenty-five animals a volume of the vaccine containing a quantity of virus equivalent to the minimum titre stated on the label. Keep not fewer than ten animals as controls. Observe all the animals for 180 days. No animal shows signs of rabies. The test is not valid if fewer than twenty-five vaccinated animals survive after this observation period. On the 180th day after vaccination, challenge all foxes by the intramuscular injection of virulent rabies virus of a strain approved by the competent authority. Observe the animals for 90 days. Animals that die from causes not attributable to rabies are eliminated. The test is not valid if the number of such deaths reduces the number of vaccinated animals in the test to fewer than twenty-five. The vaccine complies with the test if not more than two of twenty-five vaccinated animals (or a statistically equivalent number if more than twenty-five vaccinated animals are challenged) show signs of rabies. The test is not valid unless at least nine control animals (or a statistically equivalent number if more than ten control animals are challenged) show signs of rabies and the presence of rabies virus in their brain is demonstrated by the fluorescent-antibody test or some other reliable method.

LABELLING

The label states the nature of the genetic marker of the virus strain.

01/2005:0064
corrected**SWINE ERYSIPELAS VACCINE
(INACTIVATED)****Vaccinum erysipelatis suillae inactivatum****DEFINITION**

Swine erysipelas vaccine (inactivated) is a preparation of one or more suitable strains of *Erysipelothrix rhusiopathiae* (*E. insidiosa*) inactivated by a suitable method. This monograph applies to vaccines intended to protect pigs against swine erysipelas.

PRODUCTION

The vaccine may contain an adjuvant.

CHOICE OF VACCINE COMPOSITION

The vaccine is shown to be satisfactory with respect to safety (5.2.6) and efficacy (5.2.7).

Immunogenicity. The test described under Potency is suitable to demonstrate immunogenicity of the vaccine with respect to *E. rhusiopathiae* serotypes 1 and 2. If claims are made concerning another serotype, then a further test to demonstrate immunogenicity against this serotype is necessary.

BATCH TESTING

Batch potency test. The test described under Potency is not carried out for routine testing of batches of vaccine. It is carried out, for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable validated alternative test is carried out, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Use mice of a suitable strain (for example, NMRI) weighing 17-20 g, from a uniform stock and that do not have antibodies against swine erysipelas. Administer the vaccine to be examined to a group of 10 mice. Inject a suitable dose (usually 1/10 of the pig dose) subcutaneously into each mouse. At a given interval (for example, 21-28 days), depending on the vaccine to be examined, bleed the animals under anaesthesia. Pool the sera, using an equal volume from each mouse. Determine the level of antibodies by a suitable immunochemical method (2.7.1), for example, enzyme-linked immunosorbent assay with *erysipelas ELISA coating antigen BRP*. The antibody level is not significantly less than that obtained with a batch that has given satisfactory results in the test described under Potency.

IDENTIFICATION

Injected into animals that do not have antibodies against *E. rhusiopathiae*, it stimulates the production of such antibodies.

TESTS

Safety. Use pigs of the minimum age recommended for vaccination and preferably having no antibodies against swine erysipelas or, where justified, use pigs with a low level of such antibodies as long as they have not been vaccinated against Swine erysipelas and administration of the vaccine does not cause an anamnestic response. Administer a double dose of vaccine by a recommended route to each of 2 pigs. Observe the animals for 14 days. No abnormal local or systemic reaction occurs.

Sterility. It complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

If the vaccine contains more than 1 serotype, a test for 2 serotypes may be carried out on a single group by injecting each challenge serotype on different flanks of the animals. Validation and acceptance criteria are applied separately to the respective injection sites. If the vaccine contains more than 1 serotype, the potency test may also be carried out using a separate group for each serotype.

Use not fewer than 15 pigs not less than 12 weeks old, weighing not less than 20 kg and that do not have antibodies against swine erysipelas. Divide the animals into 2 groups. Vaccinate a group of not fewer than 10 pigs according to the recommended schedule. Maintain a group of not fewer than 5 pigs as unvaccinated controls. 3 weeks after vaccination, challenge the vaccinated animals and the control group by separate intradermal injections of 0.1 ml of a virulent strain of each of serotype 1 and serotype 2 of *E. rhusiopathiae*. Observe the animals for 7 days. The vaccine complies with the test if not fewer than 90 per cent of the vaccinated animals remain free from diamond skin lesions at the injection site. The test is invalid if fewer than 80 per cent of control animals show typical signs of disease, i.e. diamond skin lesions at the injection sites.

Swine erysipelas bacteria serotype 1 BRP and *swine erysipelas bacteria serotype 2 BRP* are suitable for use as challenge strains.

LABELLING

The label states the serotypes of *E. rhusiopathiae* included in the vaccine.

01/2005:0065

**SWINE-FEVER VACCINE (LIVE),
CLASSICAL, FREEZE-DRIED****Vaccinum pestis classicae suillae vivum
cryodesiccatum****DEFINITION**

Freeze-dried classical swine-fever vaccine (live) is a preparation obtained from a strain of classical swine-fever virus which has lost its pathogenicity for the pig by adaptation either to cell cultures or to the rabbit.

PRODUCTION

For vaccine prepared in rabbits, the seed-lot (or the vaccine) is made from the homogenised organs and/or blood of rabbits from healthy colonies, sacrificed at the peak of the temperature rise following intravenous inoculation of the virus. The vaccine is freeze-dried.

CHOICE OF VACCINE STRAIN

Only a virus strain shown to be satisfactory with respect to the following characteristics may be used in the preparation of the vaccine: safety; non-transmissibility; irreversibility of attenuation; and immunogenic properties. The following tests may be used during demonstration of safety (5.2.6) and efficacy (5.2.7).

The dose of vaccine used throughout the following tests is determined by the manufacturer on the basis of prior experiments.

Tests in pigs

Selection of animals. The piglets are 6 to 7 weeks old. The sows are primiparae. All animals are healthy and must

have had no contact with swine-fever virus and serologically must be free from swine-fever and bovine viral diarrhoea antibodies. They must have a week in which to adapt themselves to the new quarters where the tests are to be carried out.

Safety

(a) Each of five piglets receives intramuscularly as a single injection ten doses of vaccine (group a).

(b) Five piglets are immunodepressed by the daily injection of 2 mg of prednisolone per kilogram of body mass for five consecutive days and on the third day they receive one dose of vaccine (group b).

The animals of groups (a) and (b) are observed for 21 days. They must remain in good health. The temperature curve and the weight curve must not differ significantly from those of control animals.

(c) Ten non-immune pregnant sows each receive two doses of vaccine intramuscularly as a single injection between the twenty-fifth and thirty-fifth days of gestation. Ten non-immune pregnant sows of the same age and of the same origin receive instead of the two doses of vaccine an equal volume of a 9 g/l solution of *sodium chloride R*. The vaccinal virus does not cause abnormalities in the gestation or in the piglets.

Non-transmissibility. Twelve piglets of the same origin are kept together. Six are vaccinated in the normal way and the six others are kept as contact controls. After 40 days, all the pigs are challenged by intramuscular inoculation of a sufficient quantity of the challenge virus (see Potency) to kill an unvaccinated piglet in 7 days. The vaccinated piglets resist challenge whereas the contact piglets must display the typical signs of swine fever.

Irreversibility of attenuation. Each of two piglets receives one dose of vaccine intramuscularly. Seven days later, 5 ml of blood is taken from each of the piglets and the samples are pooled. 5 ml of the pooled blood is injected intramuscularly into each of two other piglets. This operation is repeated six times. The animals must not display any sign of swine fever and must show normal growth.

Immunogenic properties. The immunogenic properties may be demonstrated by the method described for the determination of potency. The quantity of the vaccinal virus corresponding to one dose of vaccine contains at least 100 PD₅₀.

IDENTIFICATION

A. For vaccines prepared in rabbits and lapinised vaccines prepared in cell cultures, inject intravenously 0.5 ml of the vaccine reconstituted as stated on the label into one or more non-immunised rabbits and one or more rabbits immunised either with an identical dose of a vaccine of the same type injected by the same route at least 10 days and at most 2 months beforehand or with a sufficient dose of antiserum administered a few hours before the injection of the vaccine. Measure the temperature of the rabbits in the morning and the evening starting 24 h after the injection and continuing until the fifth day after the injection. The vaccine is identified by its specific pyrogenic character leading to a rise in temperature of at least 1.5 °C in the non-immunised rabbits only.

B. For non-lapinised vaccines prepared in cell cultures, the serum of pigs immunised with the vaccine neutralises the virus used in the preparation of the vaccine.

TESTS

Safety. Use three piglets complying with the requirements prescribed for the selection of animals under Choice of Vaccine Strain. Inject intramuscularly into each piglet ten doses of the reconstituted vaccine as a single injection. Observe the animals for 21 days. The temperature curve remains normal and the animals remain in apparent good health and display normal growth.

Extraneous viruses. Mix the vaccine with a monospecific antiserum and inoculate into susceptible cell cultures. No cytopathic effect is produced.

Carry out a haemagglutination test using chicken red blood cells and the supernatant liquid of the cell cultures. The test is negative. Carry out a haemadsorption test on the cell cultures. The test is negative.

Use ten mice each weighing 11 g to 15 g. Inject intracerebrally into each mouse 0.03 ml of the vaccine reconstituted so that 1 ml contains 1 dose. Observe the animals for 21 days. If more than two mice die within the first 48 h, repeat the test. From the third to the twenty-first day after the injection, the mice show no abnormalities attributable to the vaccine.

Bacterial and fungal contamination. The vaccine to be examined complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

Mycoplasmas (2.6.7). The vaccine complies with the test for mycoplasmas.

POTENCY

The potency is expressed as the number of 50 per cent protective doses (PD₅₀) for pigs contained in the dose indicated on the label. The vaccine contains at least 100 PD₅₀ per dose.

Use piglets complying with the requirements for selection of animals described under Choice of Vaccine Strain. To two groups of five piglets inject intramuscularly:

- 1/40 of a dose of the vaccine to be examined into each piglet of the first group,
- 1/160 of a dose of the vaccine to be examined into each piglet of the second group.

Use two piglets as controls.

Prepare the dilutions using *buffered salt solution pH 7.2 R*. On the fourteenth day after the injection, inoculate intramuscularly into each vaccinated and control animal a sufficient quantity of challenge virus to kill an unvaccinated piglet in 7 days. The challenge virus preparation consists of blood of pigs infected experimentally by virus that has not been submitted to passage in cell cultures. The control animals die within the seven days of inoculation. Observe the vaccinated animals for 14 days. From the number of animals which survive without showing any sign of swine fever, calculate the number of PD₅₀ contained in the vaccine using the usual statistical methods.

LABELLING

The label states that the vaccine has been prepared in cell cultures or in rabbits as appropriate.

01/2005:0697
corrected

TETANUS VACCINE FOR VETERINARY USE

Vaccinum tetani ad usum veterinarium

DEFINITION

Tetanus vaccine for veterinary use is a preparation of the neurotoxin of *Clostridium tetani* treated in a manner that eliminates toxicity while maintaining adequate immunogenic properties.

PRODUCTION

The *C. tetani* strain used for production is cultured in a suitable medium. The toxin is purified and then detoxified or it may be detoxified before purification. The antigenic purity is determined in Lf units of tetanus toxoid per milligram of protein and shown to be not less than the value approved for the particular product.

CHOICE OF VACCINE COMPOSITION

The *C. tetani* strain used in the preparation of the vaccine is shown to be satisfactory with respect to the production of the neurotoxin. The vaccine is shown to be satisfactory with respect to safety and immunogenicity for each species of animal for which it is intended. As part of the studies to demonstrate these characteristics, the tests described below may be used.

Production of antigens. The production of the neurotoxin of *C. tetani* is verified by a suitable immunochemical method (2.7.1) carried out on the neurotoxin obtained from the vaccine strain under the conditions used for the production of the vaccine.

Safety. Carry out the test for each recommended route of administration and species of animal for which the vaccine is intended; use animals of the minimum age recommended for vaccination and of the most sensitive category for the species.

Use not fewer than 15 animals, free from antitoxic antibodies for each test. Administer a double dose of vaccine to each animal. Administer a single dose of vaccine to each animal after the interval stated on the label. Observe the animals until 14 days after the last administration. If the vaccine is intended for use in pregnant animals, vaccinate the animals at the stage of pregnancy and according to the scheme stated on the label and prolong the observation period until 1 day after parturition. The vaccine complies with the test if no animal shows abnormal local or systemic signs of disease or dies from causes attributable to the vaccine. If the vaccine is intended for use in pregnant animals, in addition no significant effects on the gestation and the offspring are demonstrated.

Immunogenicity. The test described under Potency may be used to demonstrate immunogenicity. It shall also be demonstrated for each target species that the vaccine, administered by the recommended route, stimulates an immune response consistent with the claims for the product (for example, induction of antitoxic antibodies or induction of protective levels of antitoxic antibodies).

DETOXIFIED HARVEST

Absence of toxin and irreversibility of toxoid: carry out a test for reversion to toxicity on the detoxified harvest using 2 groups of 5 guinea-pigs, each weighing 350 g to 450 g; if the vaccine is adsorbed, carry out the test with the

shortest practical time interval before adsorption. Prepare a dilution of the detoxified harvest so that the guinea-pigs each receive 10 times the amount of toxoid (measured in Lf units) that will be present in a dose of vaccine. Divide the dilution into 2 equal parts. Keep one part at $5 \pm 3^\circ\text{C}$ and the other at 37°C for 6 weeks. Attribute each dilution to a separate group of guinea-pigs and inject into each guinea-pig the dilution attributed to its group. Observe the animals for 21 days. The toxoid complies with the test if no guinea-pig shows clinical signs of disease or dies from causes attributable to the neurotoxin of *C. tetani*.

BATCH POTENCY TEST

Where the test described under Potency is used as the batch potency test, the vaccine complies with the test if the antibody titre in International Units is not less than that found for a batch of vaccine shown to be satisfactory with respect to immunogenicity in the target species.

IDENTIFICATION

If the nature of the adjuvant allows it, carry out test A. Otherwise carry out test B.

- Dissolve in the vaccine sufficient sodium citrate R to give a 100 g/l solution. Maintain the solution at 37°C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The supernatant reacts with a suitable tetanus antitoxin, giving a precipitate.
- When injected into susceptible animals, the vaccine provokes the formation of antibodies against the neurotoxin of *C. tetani*.

TESTS

Safety. Inject 5 ml of the vaccine subcutaneously as 2 equal divided doses, at separate sites into each of 5 healthy guinea-pigs, each weighing 350 g to 450 g, that have not previously been treated with any material that will interfere with the test. No abnormal local or systemic reaction occurs. If within 21 days of the injection any of the animals shows signs of or dies from tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test. If any animal dies in the second test, the vaccine does not comply with the test.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Administer 1 dose of vaccine subcutaneously to each of at least 5 susceptible guinea-pigs. After 28 days, administer again 1 dose subcutaneously to each guinea-pig. 14 days after the second dose, collect blood from each guinea-pig and prepare serum samples. Determine for each serum the titre of antibodies against the neurotoxin of *C. tetani* using a suitable immunochemical method (2.7.1) such as a toxin-binding-inhibition test (ToBI test) and a homologous reference serum. Determine the average antibody titre of the serum samples.

Clostridia (multicomponent) rabbit antiserum BRP, Clostridium tetani guinea-pig antiserum for vaccines for veterinary use BRP and Clostridium tetani rabbit antiserum BRP are suitable as reference sera.

Tetanus vaccine intended for use in animals other than horses complies with the test if the average antibody titre is not less than 7.5 IU/ml.

Tetanus vaccine intended for use in horses complies with the test if the average antibody titre is not less than 30 IU/ml.

For tetanus vaccine presented as a combined vaccine for use in animals other than horses, the above test may be carried out in susceptible rabbits instead of guinea-pigs. The vaccine complies with the test if the average antibody titre of the sera of the vaccinated rabbits is not less than 2.5 IU/ml.

01/2005:1580

VIBRIOSIS (COLD-WATER) VACCINE (INACTIVATED) FOR SALMONIDS

Vaccinum vibriosidis aquae frigidae inactivatum ad salmonidas

DEFINITION

Cold-water vibriosis vaccine (inactivated) for salmonids is prepared from cultures of one or more suitable strains of *Vibrio salmonicida*.

PRODUCTION

The strains of *V. salmonicida* are cultured and harvested separately. The harvests are inactivated by a suitable method. They may be purified and concentrated. Whole or disrupted cells may be used and the vaccine may contain extracellular products of the bacterium released into the growth medium.

CHOICE OF VACCINE COMPOSITION

The strain or strains of *V. salmonicida* used are shown to be suitable with respect to production of antigens of assumed immunological importance. The vaccine is shown to be satisfactory with respect to safety (5.2.6) and immunogenicity (5.2.7) in the species of fish for which it is intended. The following tests may be used during demonstration of safety and immunogenicity.

Safety. Safety is tested in three different batches using test A, test B or both, depending on the recommendations for use.

A. Vaccines intended for administration by injection.

A test is carried out in each species of fish for which the vaccine is intended. The fish used are from a population that does not have specific antibodies against *V. salmonicida* and which has not been vaccinated against nor exposed to cold-water vibriosis. The test is carried out in the conditions recommended for the use of the vaccine with a water temperature not less than 10 °C. An amount of vaccine corresponding to twice the recommended dose per mass unit for fish of the minimum body mass recommended for vaccination is administered intraperitoneally to each of not fewer than fifty fish of the minimum recommended body mass. The fish are observed for 21 days. No abnormal local or systemic reaction occurs. The test is invalid if more than 6 per cent of the fish die from causes not attributable to the vaccine.

B. Vaccines intended for administration by immersion.

A test is carried out in each species of fish for which the vaccine is intended. The fish used are from a population that does not have specific antibodies against *V. salmonicida* and which has not been vaccinated against nor exposed to cold-water vibriosis. The test is carried out in the conditions recommended for the use of the vaccine with a water temperature not less than 10 °C. Prepare an immersion bath at twice the recommended concentration. Not fewer than fifty fish, having not less than the minimum body mass recommended for vaccination are used. The fish are bathed for twice the recommended time. The fish are observed for 21 days. No abnormal local or systemic reaction occurs. The test is invalid if more than 6 per cent of the fish die from causes not attributable to the vaccine.

C. Safety is demonstrated in addition in field trials by administering the intended dose to a sufficient number of fish distributed in not fewer than two sets of premises. No abnormal reaction occurs.

Immunogenicity. The test described under Potency, carried out for each recommended route of administration, is suitable to demonstrate immunogenicity of the vaccine.

BATCH TESTING

Batch potency test. For routine testing of batches of vaccine, the test described under Potency may be carried out using groups of not fewer than thirty fish of one of the species for which the vaccine is intended; alternatively, a suitable validated test based on antibody response may be carried out, the criteria being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Use fish from a population that does not have specific antibodies against *V. salmonicida* and that are within specified limits for body mass. Carry out the test at a defined temperature. Inject into each of not fewer than twenty-five fish one dose of vaccine, according to the instructions for use. Perform mock vaccination on a control group of not fewer than ten fish. Collect blood samples at a defined time after vaccination. Determine for each sample the level of specific antibodies against *V. salmonicida* by a suitable immunochemical method (2.7.1). The vaccine complies with the test if the mean level of antibodies is not significantly lower than that found for a batch that gave satisfactory results in the test described under Potency. The test is not valid if the control group shows antibodies against *V. salmonicida*.

IDENTIFICATION

When injected into fish that do not have specific antibodies against *V. salmonicida*, the vaccine stimulates the production of such antibodies.

TESTS

Safety. Use not fewer than ten fish of one of the species for which the vaccine is intended, having, where possible, the minimum body mass recommended for vaccination; if fish of the minimum body mass are not available, use fish not greater than twice this mass. Use fish from a population that does not have specific antibodies against *V. salmonicida* and that has not been vaccinated against nor exposed to cold-water vibriosis. Carry out the test in the conditions recommended for use of the vaccine with a water temperature not less than 10 °C. For vaccines administered by injection or immersion, inject intraperitoneally into each fish an amount of vaccine corresponding to twice the recommended dose per mass unit. For vaccines administered by immersion only, use a bath with double the recommended concentration and bathe the fish for twice the recommended immersion time. Observe the animals for 21 days. No abnormal local or systemic reaction attributable to the vaccine occurs. The test is invalid if more than 10 per cent of the fish die from causes not attributable to the vaccine.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use* (0062).

POTENCY

Carry out the test according to a protocol defining limits of body mass for the fish, water source, water flow and temperature limits, and preparation of a standardised challenge. Vaccinate not fewer than one hundred fish by a

recommended route, according to the instructions for use. Perform mock vaccination on a control group of not fewer than one hundred fish; mark vaccinated and control fish for identification. Keep all the fish in the same tank or mix equal numbers of controls and vaccinates in each tank if more than one tank is used. Carry out challenge by injection at a fixed time interval after vaccination, defined according to the statement regarding development of immunity. Use for challenge a culture of *V. salmonicida* whose virulence has been verified. Observe the fish daily until at least 60 per cent specific mortality is reached in the control group. Plot for both vaccinates and controls a curve of specific mortality against time from challenge and determine by interpolation the time corresponding to 60 per cent specific mortality in controls. The test is invalid if the specific mortality is less than 60 per cent in the control group 21 days after the first death in the fish. Read from the curve for vaccinates the mortality (*M*) at the time corresponding to 60 per cent mortality in controls. Calculate the relative percentage survival (RPS) from the expression:

$$\left(1 - \frac{M}{60}\right) \times 100$$

The vaccine complies with the test if the RPS is not less than 60 per cent for vaccines administered by immersion and 90 per cent for vaccines administered by injection.

LABELLING

The label states information on the time needed for development of immunity after vaccination under the range of conditions corresponding to the recommended use.

01/2005:1581

VIBRIOSIS VACCINE (INACTIVATED) FOR SALMONIDS

Vaccinum vibriosidis ad salmonidas inactivatum

DEFINITION

Vibriosis vaccine (inactivated) for salmonids is prepared from cultures of one or more suitable strains or serovars of *Vibrio anguillarum*; the vaccine may also include *Vibrio ordalii*.

PRODUCTION

The strains of *V. anguillarum* and *V. ordalii* are cultured and harvested separately. The harvests are inactivated by a suitable method. They may be purified and concentrated. Whole or disrupted cells may be used and the vaccine may contain extracellular products of the bacterium released into the growth medium.

CHOICE OF VACCINE COMPOSITION

The strains of *V. anguillarum* and *V. ordalii* used are shown to be suitable with respect to production of antigens of assumed immunological importance. The vaccine is shown to be satisfactory with respect to safety (5.2.6) and immunogenicity (5.2.7) in the species of fish for which it is intended. The following tests may be used during demonstration of safety and immunogenicity.

Safety. Safety is tested in three different batches using test A, test B or both, depending on the recommendations for use.

A. *Vaccines intended for administration by injection.* A test is carried out in each species of fish for which the vaccine is intended. The fish used are from a population that does

not have specific antibodies against the relevant serovars of *V. anguillarum* or where applicable *V. ordalii* and which has not been vaccinated against nor exposed to vibriosis. The test is carried out in the conditions recommended for the use of the vaccine with a water temperature not less than 10 °C. An amount of vaccine corresponding to twice the recommended dose per mass unit for fish of the minimum body mass recommended for vaccination is administered intraperitoneally to each of not fewer than fifty fish of the minimum recommended body mass. The fish are observed for 21 days. No abnormal local or systemic reaction occurs. The test is invalid if more than 6 per cent of the fish die from causes not attributable to the vaccine.

B. *Vaccines intended for administration by immersion.* A test is carried out in each species of fish for which the vaccine is intended. The fish used are from a population that does not have specific antibodies against the relevant serovars of *V. anguillarum* or where applicable *V. ordalii* and which has not been vaccinated against nor exposed to vibriosis. The test is carried out in the conditions recommended for the use of the vaccine with a water temperature not less than 10 °C. Prepare an immersion bath at twice the recommended concentration. Not fewer than fifty fish having the minimum body mass recommended for vaccination are used. The fish are bathed for twice the recommended time. The fish are observed for 21 days. No abnormal local or systemic reaction occurs. The test is invalid if more than 6 per cent of the fish die from causes not attributable to the vaccine.

C. Safety is also demonstrated in field trials by administering the intended dose to a sufficient number of fish distributed in not fewer than two sets of premises. No abnormal reaction occurs.

Immunogenicity. The test described under Potency, carried out for each recommended route of administration is suitable to demonstrate immunogenicity of the vaccine.

BATCH TESTING

Batch potency test. For routine testing of batches of vaccine, the test described under Potency may be carried out using groups of not fewer than thirty fish of one of the species for which the vaccine is intended; alternatively, a suitable validated test based on antibody response may be carried out, the criteria being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Use fish from a population that does not have specific antibodies against the relevant serovars of *V. anguillarum* and where applicable *V. ordalii* and that are within specified limits for body mass. Carry out the test at a defined temperature. Inject into each of not fewer than twenty-five fish one dose of vaccine, according to the instructions for use. Perform mock vaccination on a control group of not fewer than ten fish. Collect blood samples at a defined time after vaccination. Determine for each sample the level of specific antibodies against the different serovars of *V. anguillarum* and against *V. ordalii* included in the vaccine by a suitable immunochemical method (2.7.1). The vaccine complies with the test if the mean levels of antibodies are not significantly lower than those found for a batch that gave satisfactory results in the test described under Potency. The test is not valid if the control group shows antibodies against the relevant serovars of *V. anguillarum* or, where applicable, against *V. ordalii*.

IDENTIFICATION

When injected into fish that do not have specific antibodies against *V. anguillarum* and, where applicable, *V. ordalii*, the vaccine stimulates the production of such antibodies.

TESTS

Safety. Use not fewer than ten fish of one of the species for which the vaccine is intended, having, where possible, the minimum body mass recommended for vaccination; if fish of the minimum body mass are not available, use fish not greater than twice this mass. Use fish from a population that does not have specific antibodies against the relevant serovars of *V. anguillarum* and, where applicable, *V. ordalii* and which has not been vaccinated against nor exposed to vibriosis. Carry out the test in the conditions recommended for the use of the vaccine with a water temperature not less than 10 °C. For vaccines administered by injection or immersion, inject intraperitoneally into each fish an amount of vaccine corresponding to twice the recommended dose per mass unit. For vaccines administered by immersion only, use a bath with double the recommended concentration and bathe the fish for twice the recommended immersion time. Observe the animals for 21 days. No abnormal local or systemic reaction attributable to the vaccine occurs. The test is invalid if more than 10 per cent of the fish die from causes not attributable to the vaccine.

Sterility. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

POTENCY

Carry out a separate test for each species and each serovar included in the vaccine. Carry out the test according to a protocol defining limits of body mass for the fish, water source, water flow and temperature limits, and preparation of a standardised challenge. Vaccinate not fewer than

one hundred fish by a recommended route, according to the instructions for use. Perform mock vaccination on a control group of not fewer than one hundred fish; mark vaccinated and control fish for identification. Keep all the fish in the same tank or mix equal numbers of controls and vaccinates in each tank if more than one tank is used. Carry out challenge by injection at a fixed time interval after vaccination, defined according to the statement regarding development of immunity. Use for challenge cultures of *V. anguillarum* or *V. ordalii* whose virulence has been verified. Observe the fish daily until at least 60 per cent specific mortality is reached in the control group. Plot for both vaccinates and controls a curve of specific mortality against time from challenge and determine by interpolation the time corresponding to 60 per cent specific mortality in controls. The test is invalid if the specific mortality is less than 60 per cent in the control group 21 days after the first death in the fish. Read from the curve for vaccinates the mortality (*M*) at the time corresponding to 60 per cent mortality in controls. Calculate the relative percentage survival (RPS) from the expression:

$$\left(1 - \frac{M}{60}\right) \times 100$$

The vaccine complies with the test if the RPS is not less than 60 per cent for vaccines administered by immersion and 75 per cent for vaccines administered by injection.

LABELLING

The label states:

- the serovar or serovars of *V. anguillarum* included in the vaccine,
- where applicable, that the vaccine includes *V. ordalii*,
- information on the time needed for development of immunity after vaccination under the range of conditions corresponding to the recommended use.

01/2005:0085

BOTULINUM ANTITOXIN**Immunoserum botulinicum****DEFINITION**

Botulinum antitoxin is a preparation containing antitoxic globulins that have the power of specifically neutralising the toxins formed by *Clostridium botulinum* type A, type B or type E, or any mixture of these types.

PRODUCTION

It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against *Cl. botulinum* type A, type B and type E toxins.

IDENTIFICATION

It specifically neutralises the types of *Cl. botulinum* toxins stated on the label, rendering them harmless to susceptible animals.

POTENCY

Not less than 500 IU of antitoxin per millilitre for each of types A and B and not less than 50 IU of antitoxin per millilitre for type E.

The potency of botulinum antitoxin is determined by comparing the dose necessary to protect mice against the lethal effects of a fixed dose of botulinum toxin with the quantity of the standard preparation of botulinum antitoxin necessary to give the same protection. For this comparison a reference preparation of each type of botulinum antitoxin, calibrated in International Units, and suitable preparations of botulinum toxins, for use as test toxins, are required. The potency of each test toxin is determined in relation to the specific reference preparation; the potency of the botulinum antitoxin to be examined is determined in relation to the potency of the test toxins by the same method.

International Units of the antitoxin are the specific neutralising activity for botulinum toxin type A, type B and type E contained in stated amounts of the International Standards which consist of dried immune horse sera of types A, B and E. The equivalence in International Units of the International Standard is stated from time to time by the World Health Organisation.

Selection of animals. Use mice having body masses such that the difference between the lightest and the heaviest does not exceed 5 g.

Preparation of test toxins. **CAUTION: Botulinum toxin is extremely toxic: exceptional care must be taken in any procedure in which it is employed.** Prepare type A, B and E toxins from sterile filtrates of approximately 7-day cultures in liquid medium of *Cl. botulinum* types A, B and E. To the filtrates, add 2 volumes of glycerol, concentrate, if necessary, by dialysis against glycerol and store at or slightly below 0 °C.

Selection of test toxins. Select toxins of each type for use as test toxins by determining for mice the L₊/10 dose and the LD₅₀, the observation period being 96 h. The test toxins contain at least 1000 LD₅₀ in an L₊/10 dose.

Determination of test doses of the toxins (L₊/10 dose).

Prepare solutions of the reference preparations in a suitable liquid such that each contains 0.25 IU of antitoxin per millilitre. Using each solution in turn, determine the test dose of the corresponding test toxin.

Prepare mixtures of the solution of the reference preparation and the test toxin such that each contains 2.0 ml of the solution of the reference preparation, one of a graded series

of volumes of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using four mice for each mixture, inject a dose of 1.0 ml intraperitoneally into each mouse. Observe the mice for 96 h. The test dose of toxin is the quantity in 1.0 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, the death of all four mice injected with the mixture within the observation period.

Determination of potency of the antitoxin. Prepare solutions of each reference preparation in a suitable liquid such that each contains 0.25 IU of antitoxin per millilitre.

Prepare solutions of each test toxin in a suitable liquid such that each contains 2.5 test doses per millilitre.

Using each toxin solution and the corresponding reference preparation in turn, determine the potency of the antitoxin. Prepare mixtures of the solution of the test toxin and the antitoxin to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined, and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (2.0 ml) that contains 0.5 IU, and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using four mice for each mixture, inject a dose of 1.0 ml intraperitoneally into each mouse. Observe the mice for 96 h.

The mixture that contains the largest volume of antitoxin that fails to protect the mice from death contains 0.5 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the mice injected with mixtures containing 2.0 ml or less of the solution of the reference preparation die and all those injected with mixtures containing more survive.

LABELLING

The label states the types of *Cl. botulinum* toxin neutralised by the preparation.

01/2005:0086

DIPHTHERIA ANTITOXIN**Immunoserum diphthericum****DEFINITION**

Diphtheria antitoxin is a preparation containing antitoxic globulins that have the power of specifically neutralising the toxin formed by *Corynebacterium diphtheriae*.

PRODUCTION

It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against diphtheria toxin.

IDENTIFICATION

It specifically neutralises the toxin formed by *C. diphtheriae*, rendering it harmless to susceptible animals.

ASSAY

Not less than 1000 IU of antitoxin per millilitre for antitoxin obtained from horse serum. Not less than 500 IU of antitoxin per millilitre for antitoxin obtained from the serum of other mammals.

The potency of diphtheria antitoxin is determined by comparing the dose necessary to protect guinea-pigs or rabbits against the erythrogenic effects of a fixed dose of diphtheria toxin with the quantity of the standard preparation of diphtheria antitoxin necessary to give the same protection. For this comparison a reference preparation of diphtheria antitoxin, calibrated in International Units, and a suitable preparation of diphtheria toxin, for use as a test toxin, are required. The potency of the test toxin is determined in relation to the reference preparation; the potency of the diphtheria antitoxin to be examined is determined in relation to the potency of the test toxin by the same method.

The International Unit of antitoxin is the specific neutralising activity for diphtheria toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Preparation of test toxin. Prepare diphtheria toxin from cultures of *C. diphtheriae* in a liquid medium. Filter the culture to obtain a sterile toxic filtrate and store at 4 °C.

Selection of test toxin. Select a toxin for use as a test toxin by determining for guinea-pigs or rabbits the $lr/100$ dose and the minimal reacting dose, the observation period being 48 h. The test toxin has at least 200 minimal reacting doses in the $lr/100$ dose.

Minimal reacting dose. This is the smallest quantity of toxin which, when injected intracutaneously into guinea-pigs or rabbits, causes a small, characteristic reaction at the site of injection within 48 h.

The test toxin is allowed to stand for some months before being used for the assay of antitoxin. During this time its toxicity declines and the $lr/100$ dose may be increased. Determine the minimal reacting dose and the $lr/100$ dose at frequent intervals. When experiment shows that the $lr/100$ dose is constant, the test toxin is ready for use and may be used for a long period. Store the test toxin in the dark at 0 °C to 5 °C. Maintain its sterility by the addition of toluene or other antimicrobial preservative that does not cause a rapid decline in specific toxicity.

Determination of test dose of toxin ($lr/100$ dose). Prepare a solution of the reference preparation in a suitable liquid such that it contains 0.1 IU of antitoxin per millilitre.

Prepare mixtures of the solution of the reference preparation and of the test toxin such that each contains 1.0 ml of the solution of the reference preparation, one of a graded series of volumes of the test toxin and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 15 min to 60 min. Using two animals for each mixture, inject a dose of 0.2 ml intracutaneously into the shaven or depilated flanks of each animal. Observe the animals for 48 h.

The test dose of toxin is the quantity in 0.2 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, a small but characteristic erythematous lesion at the site of injection.

Determination of potency of the antitoxin. Prepare a solution of the reference preparation in a suitable liquid such that it contains 0.125 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that it contains 12.5 test doses per millilitre.

Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined such that each contains 0.8 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 0.8 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (0.8 ml) that contains 0.1 IU and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 15 min to 60 min. Using two animals for each mixture, inject a dose of 0.2 ml intracutaneously into the shaven or depilated flanks of each animal. Observe the animals for 48 h.

The mixture that contains the largest volume of antitoxin that fails to protect the guinea-pigs from the erythematous effects of the toxin contains 0.1 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the sites injected with mixtures containing 0.8 ml or less of the solution of the reference preparation show erythematous lesions and at all those injected with mixtures containing more there are no lesions.

01/2005:0090

GAS-GANGRENE ANTITOXIN, MIXED

Immunoserum gangraenicum mixtum

DEFINITION

Mixed gas-gangrene antitoxin is prepared by mixing gas-gangrene antitoxin (novyi), gas-gangrene antitoxin (perfringens) and gas-gangrene antitoxin (septicum) in appropriate quantities.

IDENTIFICATION

It specifically neutralises the alpha toxins formed by *Clostridium novyi* (former nomenclature: *Clostridium oedematiens*), *Clostridium perfringens* and *Clostridium septicum*, rendering them harmless to susceptible animals.

ASSAY

Gas-gangrene antitoxin (novyi), not less than 1000 IU of antitoxin per millilitre; gas-gangrene antitoxin (perfringens), not less than 1000 IU of antitoxin per millilitre; gas-gangrene antitoxin (septicum) not less than 500 IU of antitoxin per millilitre.

Carry out the assay for each component, as prescribed in the monographs on *Gas-gangrene antitoxin (novyi)* (0087), *Gas-gangrene antitoxin (perfringens)* (0088) and *Gas-gangrene antitoxin (septicum)* (0089).

01/2005:0087

GAS-GANGRENE ANTITOXIN (NOVYI)

Immunoserum gangraenicum
(*Clostridium novyi*)

DEFINITION

Gas-gangrene antitoxin (novyi) is a preparation containing antitoxic globulins that have the power of neutralising the alpha toxin formed by *Clostridium novyi* (Former

nomenclature: *Clostridium oedematiens*). It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against *Cl. novyi* alpha toxin.

IDENTIFICATION

It specifically neutralises the alpha toxin formed by *Cl. novyi*, rendering it harmless to susceptible animals.

ASSAY

Not less than 3750 IU of antitoxin per millilitre.

The potency of gas-gangrene antitoxin (novyi) is determined by comparing the dose necessary to protect mice or other suitable animals against the lethal effects of a fixed dose of *Cl. novyi* toxin with the quantity of the standard preparation of gas-gangrene antitoxin (novyi) necessary to give the same protection. For this comparison a reference preparation of gas-gangrene antitoxin (novyi), calibrated in International Units, and a suitable preparation of *Cl. novyi* toxin for use as a test toxin are required. The potency of the test toxin is determined in relation to the reference preparation; the potency of the gas-gangrene antitoxin (novyi) to be examined is determined in relation to the potency of the test toxin by the same method.

The International Unit of antitoxin is the specific neutralising activity for *Cl. novyi* toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Selection of animals. Use mice having body masses such that the difference between the lightest and the heaviest does not exceed 5 g.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an approximately 5-day culture in liquid medium of *Cl. novyi*. Treat the filtrate with *ammonium sulphate R*, collect the precipitate, which contains the toxin, dry *in vacuo* over *diphosphorus pentoxide R*, powder and store dry.

Selection of test toxin. Select a toxin for use as a test toxin by determining for mice the L+ dose and the LD₅₀, the observation period being 72 h. The test toxin has an L+ dose of 0.5 mg or less and contains not less than 25 LD₅₀ in each L+ dose.

Determination of test dose of toxin (L+ dose). Prepare a solution of the reference preparation in a suitable liquid such that it contains 12.5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that 1 ml contains a precisely known amount such as 10 mg.

Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each contains 0.8 ml of the solution of the reference preparation, one of a graded series of volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.2 ml intramuscularly into each mouse. Observe the mice for 72 h.

The test dose of toxin is the quantity in 0.2 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, the death of all six mice injected with the mixture within the observation period.

Determination of potency of the antitoxin. Prepare a solution of the reference preparation in a suitable liquid such that it contains 12.5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that it contains 12.5 test doses per millilitre.

Prepare mixtures of the solution of the test toxin and the antitoxin to be examined such that each contains 0.8 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 0.8 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (0.8 ml) that contains 10 IU and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.2 ml intramuscularly into each mouse. Observe the mice for 72 h.

The mixture that contains the largest volume of antitoxin that fails to protect the mice from death contains 10 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the mice injected with mixtures containing 0.8 ml or less of the solution of the reference preparation die and all those injected with mixtures containing a larger volume survive.

01/2005:0088

GAS-GANGRENE ANTITOXIN (PERFRINGENS)

Immunoserum gangraenicum (*Clostridium perfringens*)

DEFINITION

Gas-gangrene antitoxin (perfringens) is a preparation containing antitoxic globulins that have the power of specifically neutralising the alpha toxin formed by *Clostridium perfringens*. It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against *Cl. perfringens* alpha toxin.

IDENTIFICATION

It specifically neutralises the alpha toxin formed by *Cl. perfringens*, rendering it harmless to susceptible animals.

ASSAY

Not less than 1500 IU of antitoxin per millilitre.

The potency of gas-gangrene antitoxin (perfringens) is determined by comparing the dose necessary to protect mice or other suitable animals against the lethal effects of a fixed dose of *Cl. perfringens* toxin with the quantity of the standard preparation of gas-gangrene antitoxin (perfringens) necessary to give the same protection. For this comparison a reference preparation of gas-gangrene antitoxin (perfringens), calibrated in International Units, and a suitable preparation of *Cl. perfringens* toxin for use as a test toxin are required. The potency of the test toxin is determined in relation to the reference preparation; the potency of the gas-gangrene antitoxin (perfringens) to be examined is determined in relation to the potency of the test toxin by the same method.

The International Unit of antitoxin is the specific neutralising activity for *Cl. perfringens* toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

01/2005:0089

Selection of animals. Use mice having body masses such that the difference between the lightest and the heaviest does not exceed 5 g.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an approximately 5-day culture in liquid medium of *Cl. perfringens*. Treat the filtrate with *ammonium sulphate R*, collect the precipitate, which contains the toxin, dry *in vacuo* over *diphosphorus pentoxide R*, powder and store dry.

Selection of test toxin. Select a toxin for use as a test toxin by determining for mice the L+ dose and the LD₅₀, the observation period being 48 h. The test toxin has an L+ dose of 4 mg or less and contains not less than 20 LD₅₀ in each L+ dose.

Determination of test dose of toxin (L+ dose). Prepare a solution of the reference preparation in a suitable liquid such that it contains 5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that 1 ml contains a precisely known amount such as 10 mg.

Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each contains 2.0 ml of the solution of the reference preparation, one of a graded series of volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.5 ml intravenously into each mouse. Observe the mice for 48 h.

The test dose of toxin is the quantity in 0.5 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, the death of all six mice injected with the mixture within the observation period.

Determination of potency of the antitoxin. Prepare a solution of the reference preparation in a suitable liquid such that it contains 5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that it contains five test doses per millilitre.

Prepare mixtures of the solution of the test toxin and the antitoxin to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (2.0 ml) that contains 10 IU and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.5 ml intravenously into each mouse. Observe the mice for 48 h.

The mixture that contains the largest volume of antitoxin that fails to protect the mice from death contains 10 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the mice injected with mixtures containing 2.0 ml or less of the solution of the reference preparation die and all those injected with mixtures containing a larger volume survive.

GAS-GANGRENE ANTITOXIN (SEPTICUM)

Immunoserum gangraenicum (*Clostridium septicum*)

DEFINITION

Gas-gangrene antitoxin (septicum) is a preparation containing antitoxic globulins that have the power of specifically neutralising the alpha toxin formed by *Clostridium septicum*. It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against *Cl. septicum* alpha toxin.

IDENTIFICATION

It specifically neutralises the alpha toxin formed by *Cl. septicum*, rendering it harmless to susceptible animals.

ASSAY

Not less than 1500 IU of antitoxin per millilitre.

The potency of gas-gangrene antitoxin (septicum) is determined by comparing the dose necessary to protect mice or other suitable animals against the lethal effects of a fixed dose of *Cl. septicum* toxin with the quantity of the standard preparation of gas-gangrene antitoxin (septicum) necessary to give the same protection. For this comparison a reference preparation of gas-gangrene antitoxin (septicum), calibrated in International Units, and a suitable preparation of *Cl. septicum* toxin for use as a test toxin are required. The potency of the test toxin is determined in relation to the reference preparation; the potency of the gas-gangrene antitoxin (septicum) to be examined is determined in relation to the potency of the test toxin by the same method.

The International Unit of antitoxin is the specific neutralising activity for *Cl. septicum* toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Selection of animals. Use mice having body masses such that the difference between the lightest and the heaviest does not exceed 5 g.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an approximately 5-day culture in liquid medium of *Cl. septicum*. Treat the filtrate with *ammonium sulphate R*, collect the precipitate, which contains the toxin, dry *in vacuo* over *diphosphorus pentoxide R*, powder and store dry.

Selection of test toxin. Select a toxin for use as a test toxin by determining for mice the L+ dose and the LD₅₀, the observation period being 72 h. The test toxin has an L+ dose of 0.5 mg or less and contains not less than 25 LD₅₀ in each L+ dose.

Determination of test dose of toxin (L+ dose). Prepare a solution of the reference preparation in a suitable liquid such that it contains 5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that 1 ml contains a precisely known amount such as 20 mg.

Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each contains 2.0 ml of the solution of the reference preparation, one of a graded series of volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature,

protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.5 ml intravenously into each mouse. Observe the mice for 72 h.

The test dose of toxin is the quantity in 0.5 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, the death of all six mice injected with the mixture within the observation period.

Determination of potency of the antitoxin. Prepare a solution of the reference preparation in a suitable liquid such that it contains 5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that it contains five test doses per millilitre.

Prepare mixtures of the solution of the test toxin and the antitoxin to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (2.0 ml) that contains 10 IU and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.5 ml intravenously into each mouse. Observe the mice for 72 h.

The mixture that contains the largest volume of antitoxin that fails to protect the mice from death contains 10 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the mice injected with mixtures containing 2.0 ml or less of the solution of the reference preparation die and all those injected with mixtures containing more survive.

01/2005:0091

TETANUS ANTITOXIN FOR HUMAN USE

Immunoserum tetanicum ad usum humanum

DEFINITION

Tetanus antitoxin for human use is a preparation containing antitoxic globulins that have the power of specifically neutralising the toxin formed by *Clostridium tetani*.

PRODUCTION

It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against tetanus toxin.

IDENTIFICATION

It specifically neutralises the toxin formed by *Cl. tetani*, rendering it harmless to susceptible animals.

POTENCY

Not less than 1000 IU of antitoxin per millilitre when intended for prophylactic use. Not less than 3000 IU of antitoxin per millilitre when intended for therapeutic use. The potency of tetanus antitoxin is determined by comparing the dose necessary to protect guinea-pigs or mice against the paralytic effects of a fixed dose of tetanus toxin with the quantity of the standard preparation of tetanus antitoxin

necessary to give the same protection. In countries where the paralysis method is not obligatory the lethal method may be used. For this method the number of animals and the procedure are identical with those described for the paralysis method but the end-point is the death of the animal rather than the onset of paralysis and the L₅₀/10 dose is used instead of the L_p/10 dose. For this comparison a reference preparation of tetanus antitoxin, calibrated in International Units, and a suitable preparation of tetanus toxin, for use as a test toxin, are required. The potency of the test toxin is determined in relation to the reference preparation; the potency of the tetanus antitoxin to be examined is determined in relation to the potency of the test toxin by the same method.

The International Unit of antitoxin is the specific neutralising activity for tetanus toxin contained in a stated amount of the International Standard which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Selection of animals. If mice are used, the body masses should be such that the difference between the lightest and the heaviest does not exceed 5 g.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an approximately 9-day culture in liquid medium of *Cl. tetani*. To the filtrate add 1 to 2 volumes of glycerol and store slightly below 0 °C. Alternatively, treat the filtrate with *ammonium sulphate R*, collect the precipitate, which contains the toxin, dry *in vacuo* over *diphosphorus pentoxide R*, powder and store dry, either in sealed ampoules or *in vacuo* over *diphosphorus pentoxide R*.

Determination of test dose of toxin (L_p/10 dose). Prepare a solution of the reference preparation in a suitable liquid such that it contains 0.5 IU of antitoxin per millilitre.

If the test toxin is stored dry, reconstitute it using a suitable liquid.

Prepare mixtures of the solution of the reference preparation and the test toxin such that each contains 2.0 ml of the solution of the reference preparation, one of a graded series of volumes of the test toxin and sufficient of a suitable liquid to bring the volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.5 ml subcutaneously into each mouse. Observe the mice for 96 h. Mice that become paralysed may be killed.

The test dose of toxin is the quantity in 0.5 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, paralysis in all six mice injected with the mixture within the observation period.

Determination of potency of the antitoxin. Prepare a solution of the reference preparation in a suitable liquid such that it contains 0.5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that it contains five test doses per millilitre.

Prepare mixtures of the solution of the test toxin and the antitoxin to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (2.0 ml) that contains 1 IU and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature,

protected from light, for 60 min. Using six mice for each mixture, inject into each mouse subcutaneously a dose of 0.5 ml. Observe the mice for 96 h. Mice that become paralysed may be killed.

The mixture that contains the largest volume of antitoxin that fails to protect the mice from paralysis contains 1 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the mice injected with mixtures containing 2.0 ml or less of the solution of the reference preparation show paralysis and all those injected with mixtures containing more do not.

01/2005:0145

VIPER VENOM ANTISERUM, EUROPEAN

Immunoserum contra venena viperarum europaeorum

DEFINITION

European viper venom antiserum is a preparation containing antitoxic globulins that have the power of neutralising the venom of one or more species of viper. The globulins are obtained by fractionation of the serum of animals that have been immunised against the venom or venoms.

IDENTIFICATION

It neutralises the venom of *Vipera ammodytes*, or *Vipera aspis*, or *Vipera berus*, or *Vipera ursinii* or the mixture of these venoms stated on the label, rendering them harmless to susceptible animals.

ASSAY

Each millilitre of the preparation to be examined contains sufficient antitoxic globulins to neutralise not less than 100 mouse LD₅₀ of *Vipera ammodytes* venom or *Vipera aspis* venom and not less than 50 mouse LD₅₀ of the venoms of other species of viper.

The potency of European viper venom antiserum is determined by estimating the dose necessary to protect mice against the lethal effects of a fixed dose of venom of the relevant species of viper.

Selection of test venoms. Use venoms which have the normal physicochemical, toxicological and immunological characteristics of venoms from the particular species of vipers. They are preferably freeze-dried and stored in the dark at 5 ± 3 °C.

Select a venom for use as a test venom by determining the LD₅₀ for mice, the observation period being 48 h.

Determination of the test dose of venom. Prepare graded dilutions of the reconstituted venom in a 9 g/l solution of *sodium chloride R* or other isotonic diluent in such a manner that the middle dilution contains in 0.25 ml the dose expected to be the LD₅₀. Dilute with an equal volume of the same diluent. Using at least four mice, each weighing 18 g to 20 g, for each dilution, inject 0.5 ml intravenously into each mouse. Observe the mice for 48 h and record the number of deaths. Calculate the LD₅₀ using the usual statistical methods.

Determination of the potency of the antiserum to be examined. Dilute the reconstituted test venom so that 0.25 ml contains the test dose of 5 LD₅₀ (test venom solution). Prepare serial dilutions of the antiserum to be examined in a 9 g/l solution of *sodium chloride R* or other isotonic diluent, the dilution factor being 1.5 to 2.5. Use a sufficient number and range of dilutions to enable a mortality curve between 20 per cent and 80 per cent mortality to be established and to permit an estimation of the statistical variation.

Prepare mixtures such that 5 ml of each mixture contains 2.5 ml of one of the dilutions of the antiserum to be examined and 2.5 ml of the test venom solution. Allow the mixtures to stand in a water-bath at 37 °C for 30 min. Using not fewer than six mice, each weighing 18 g to 20 g, for each mixture, inject 0.5 ml intravenously into each mouse. Observe the mice for 48 h and record the number of deaths. Calculate the PD₅₀, using the usual statistical methods. At the same time verify the number of LD₅₀ in the test dose of venom, using the method described above. Calculate the potency of the antiserum from the expression:

$$\frac{(T_v - 1)}{PD_{50}}$$

T_v = number of LD₅₀ in the test dose of venom.

In each mouse dose of the venom-antiserum mixture at the end point there is one LD₅₀ of venom remaining unneutralised by the antiserum and it is this unneutralised venom that is responsible for the deaths of 50 per cent of the mice inoculated with the mixture. The amount of venom neutralised by the antiserum is thus one LD₅₀ less than the total amount contained in each mouse dose. Therefore, as the potency of the antiserum is defined in terms of the number of LD₅₀ of venom that are neutralised, rather than the number of LD₅₀ in each mouse dose, the expression required in the calculation of potency is $T_v - 1$ rather than T_v . Alternatively, the quantity of test venom in milligrams that is neutralised by 1 ml or some other defined volume of the antiserum to be examined may be calculated.

LABELLING

The label states the venom or venoms against which the antiserum is effective.

Warning: Because of the allergenic properties of viper venoms, inhalation of venom dust should be avoided by suitable precautions.

01/2005:0340

CLOSTRIDIUM PERFRINGENS BETA ANTITOXIN FOR VETERINARY USE

Immunoserum clostridii perfringentis beta ad usum veterinarium

DEFINITION

Clostridium perfringens beta antitoxin for veterinary use is a preparation containing principally the globulins that have the power of specifically neutralising the beta toxin formed by *Clostridium perfringens* (types B and C). It consists of the serum or a preparation obtained from the serum of animals immunised against *Cl. perfringens* beta toxin.

IDENTIFICATION

It specifically neutralises the beta toxin of *Cl. perfringens* rendering it harmless to susceptible animals.

POTENCY

The potency of the crude serum is not less than 1000 IU/ml when obtained from horses and not less than 250 IU/ml when obtained from cattle.

The potency of the concentrated serum is not less than 3000 IU/ml when obtained from horses and not less than 1000 IU/ml when obtained from cattle.

The International Unit is the specific neutralising activity for *Cl. perfringens* beta toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of clostridium perfringens beta antitoxin is determined by comparing the dose necessary to protect mice or other suitable animals against the toxic effects of a fixed dose of *Cl. perfringens* beta toxin with the quantity of a reference preparation of clostridium perfringens beta antitoxin, calibrated in International Units, necessary to give the same protection. For this comparison, a suitable preparation of *Cl. perfringens* beta toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the reference preparation; the potency of the clostridium perfringens beta antitoxin to be examined is determined in relation to the reference preparation using the test toxin.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an early culture in liquid medium of *Cl. perfringens* type B or type C and dry by a suitable method.

Select the test toxin by determining for mice the L+ dose and the LD₅₀, the observation period being 72 h. A suitable beta toxin contains not less than one L+ dose in 0.2 mg and not less than 25 LD₅₀ in each L+ dose.

Determination of test dose of toxin. Prepare a solution of the reference preparation in a suitable liquid so that it contains 5 IU/ml. Prepare a solution of the test toxin in a suitable liquid so that 1 ml contains a precisely known amount such as 10 mg. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each mixture contains 2.0 ml of the solution of the reference preparation (10 IU), one of a series of graded volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than two mice, each weighing 17 g to 22 g, for each mixture, inject a dose of 0.5 ml intravenously or

intra-peritoneally into each mouse. Observe the mice for 72 h. If all the mice die, the amount of toxin present in 0.5 ml of the mixture is in excess of the test dose. If none of the mice dies, the amount of toxin present in 0.5 ml of the mixture is less than the test dose. Prepare fresh mixtures such that 5.0 ml of each mixture contains 2.0 ml of the solution of the reference preparation (10 IU) and one of a series of graded volumes of the solution of the test toxin separated from each other by steps of not more than 20 per cent and covering the expected end-point. Allow the mixtures to stand at room temperature for 30 min.

Using not fewer than two mice for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. Repeat the determination at least once and combine the results of the separate tests that have been made with mixtures of the same composition so that a series of totals is obtained, each total representing the mortality due to a mixture of a given composition. The test dose of toxin is the amount present in 0.5 ml of that mixture which causes the death of one half of the total number of mice injected with it.

Determination of the potency of the antitoxin to be examined

Preliminary test. Dissolve a quantity of the test toxin in a suitable liquid so that 2.0 ml contains 10 times the test dose. Prepare mixtures of the solution of the test toxin and the antitoxin to be examined such that each mixture contains 2.0 ml of the solution of the test toxin, one of a series of graded volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the final volume to 5.0 ml. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than two mice for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. If none of the mice dies, 0.5 ml of the mixture contains more than 1 IU. If all the mice die, 0.5 ml of the mixture contains less than 1 IU.

Final test. Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the antitoxin to be examined, separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined by the preliminary test. Prepare further mixtures such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the solution of the reference preparation, in order to confirm the test dose of the toxin. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than two mice for each mixture, proceed as described in the preliminary test. The test mixture which contains, in 0.5 ml, 1 IU is that mixture which kills the same or almost the same number of mice as the reference mixture containing, in 0.5 ml, 1 IU. Repeat the determination at least once and calculate the average of all valid estimates. Estimates are valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits ($P = 0.95$) have been estimated to be: 85 per cent and 114 per cent when two animals per dose are used,

91.5 per cent and 109 per cent when four animals per dose are used,

93 per cent and 108 per cent when six animals per dose are used.

LABELLING

The label states whether the product consist of crude concentrated serum.

01/2005:0341

CLOSTRIDIUM PERFRINGENS EPSILON ANTITOXIN FOR VETERINARY USE

Immunoserum clostridii perfringentis epsilon ad usum veterinarium

DEFINITION

Clostridium perfringens epsilon antitoxin for veterinary use is a preparation containing the globulins that have the power of specifically neutralising the epsilon toxin formed by *Clostridium perfringens* type D. It consists of the serum or a preparation obtained from the serum of animals immunised against *Cl. perfringens* epsilon toxin.

IDENTIFICATION

It specifically neutralises the epsilon toxin of *Cl. perfringens* type D, rendering it harmless to susceptible animals.

POTENCY

The potency of the crude serum is not less than 120 IU/ml when obtained from horses and not less than 100 IU/ml when obtained from cattle.

The potency of the concentrated serum is not less than 300 IU/ml when obtained from horses and not less than 150 IU/ml when obtained from cattle.

The International Unit is the specific neutralising activity for *Cl. perfringens* epsilon toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of clostridium perfringens epsilon antitoxin is determined by comparing the dose necessary to protect mice or other suitable animals against the toxic effects of a fixed dose of *Cl. perfringens* epsilon toxin with the quantity of a reference preparation of clostridium perfringens epsilon anti-toxin, calibrated in International Units, necessary to give the same protection. For this comparison, a suitable preparation of *Cl. perfringens* epsilon toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the reference preparation, the potency of the antitoxin to be examined is determined in relation to the reference preparation using the test toxin.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an early culture in liquid medium of *Cl. perfringens* type D and dry by a suitable method.

Select the test toxin by determining for mice the $L_{+}/10$ dose and the LD_{50} , the observation period being 72 h. A suitable epsilon toxin contains not less than one $L_{+}/10$ dose in 0.005 mg and not less than 20 LD_{50} in each $L_{+}/10$ dose.

Determination of test dose of toxin. Prepare a solution of the reference preparation in a suitable liquid so that it contains 0.5 IU of antitoxin per millilitre. Prepare a solution of the test toxin in a suitable liquid so that 1 ml contains a precisely known amount such as 1 mg. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each mixture contains 2.0 ml of the solution of the reference preparation (1 IU), one of a series of graded volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature

for 30 min. Using not fewer than two mice, each weighing 17 g to 22 g, for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. If all the mice die, the amount of toxin present in 0.5 ml of the mixture is in excess of the test dose. If none of the mice dies, the amount of toxin present in 0.5 ml of the mixture is less than the test dose.

Prepare similar fresh mixtures such that 5.0 ml of each mixture contains 2.0 ml of the solution of the reference preparation (1 IU) and one of a series of graded volumes of the solution of the test toxin, separated from each other by steps of not more than 20 per cent and covering the expected end-point. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than two mice for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. Repeat the determination at least once and add together the results of the separate tests that have been made with mixtures of the same composition so that a series of totals is obtained, each total representing the mortality due to a mixture of a given composition. The test dose of the toxin is the amount present in 0.5 ml of that mixture which causes the death of one half of the total number of mice injected with it.

Determination of the potency of the antitoxin to be examined

Preliminary test. Dissolve a quantity of the test toxin in a suitable liquid so that 2.0 ml contains 10 times the test dose (solution of the test toxin). Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined such that each mixture contains 2.0 ml of the solution of the test toxin, one of a series of graded volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the final volume to 5.0 ml. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than two mice for each mixture, inject a dose of 0.5 ml intravenously or intra-peritoneally into each mouse. Observe the mice for 72 h. If none of the mice dies, 0.5 ml of the mixture contains more than 0.1 IU. If all the mice die, 0.5 ml of the mixture contains less than 0.1 IU.

Final test. Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the antitoxin to be examined, separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined by the preliminary test. Prepare further mixtures such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the solution of the reference preparation to confirm the test dose of the toxin. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than two mice for each mixture proceed as described in the preliminary test. The test mixture which contains 0.1 IU in 0.5 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing 0.1 IU in 0.5 ml. Repeat the determination at least once and calculate the average of all valid estimates. Estimates are valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits ($P = 0.95$) have been estimated to be:

85 per cent and 114 per cent when 2 animals per dose are used,

91.5 per cent and 109 per cent when 4 animals per dose are used,

93 per cent and 108 per cent when 6 animals per dose are used.

LABELLING

The label states whether the product consists of crude or concentrated serum.

01/2005:0343

TETANUS ANTITOXIN FOR VETERINARY USE

Immunoserum tetanicum ad usum veterinarium

DEFINITION

Tetanus antitoxin for veterinary use is a preparation containing principally the globulins that have the power of specifically neutralising the neurotoxin formed by *Clostridium tetani*. It consists of the serum or a preparation obtained from the serum of animals immunised against tetanus toxin.

IDENTIFICATION

It specifically neutralises the neurotoxin formed by *Cl. tetani*, rendering it harmless to susceptible animals.

POTENCY

The potency of the crude serum is not less than 300 IU/ml when obtained from horses and not less than 150 IU/ml when obtained from cattle.

The potency of the concentrated serum is not less than 1000 IU/ml when obtained from horses and not less than 500 IU/ml when obtained from cattle.

The International Unit is the specific neutralising activity for tetanus toxin contained in a stated amount of the International Standard which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of tetanus antitoxin is determined by comparing the dose necessary to protect mice (or guinea-pigs) against the toxic effects of a fixed dose of tetanus toxin with the quantity of a reference preparation of tetanus antitoxin, calibrated in International Units, necessary to give the same protection. In countries where the paralysis method is not obligatory, the lethal method may be used. For this method the number of animals and the procedure are identical with those described for the paralysis method but the end-point is the death of the animal rather than the onset of paralysis and the L₅₀/10 dose and the LD₅₀ are used instead of the Lp/10 dose and the paralytic dose 50 per cent. For this comparison, a suitable preparation of tetanus toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the reference preparation; the potency of the antitoxin to be examined is determined in relation to the reference preparation using the test toxin.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an 8 to 10 day culture in liquid medium of *Cl. tetani*. A test toxin may be prepared by adding this filtrate to *glycerol R* in the proportion of 1 volume of filtrate to 1 to 2 volumes of *glycerol R*. The solution of test toxin may be stored at or slightly below 0 °C. The toxin may also be dried by a suitable method.

Select the test toxin by determining for mice the Lp/10 dose and the paralytic dose 50 per cent. A suitable toxin contains not less than 1000 times the paralytic dose 50 per cent in one Lp/10 dose.

Lp/10 dose (Limes paralyticum). This is the smallest quantity of toxin which when mixed with 0.1 IU of antitoxin and injected subcutaneously into mice (or guinea-pigs) causes tetanic paralysis in the animals on or before the fourth day after injection.

Paralytic dose 50 per cent. This is the quantity of toxin which when injected subcutaneously into mice (or guinea-pigs) causes tetanic paralysis in one half of the animals on or before the fourth day after injection.

Determination of test dose of toxin. Reconstitute or dilute the reference preparation with a suitable liquid so that it contains 0.5 IU per millilitre. Measure or weigh a quantity of the test toxin and dilute with or dissolve in a suitable liquid. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin so that each mixture will contain 0.1 IU of antitoxin in the volume chosen for injection and one of a series of graded volumes of the solution of the test toxin, separated from each other by steps of not more than 20 per cent and covering the expected end-point. Adjust each mixture with a suitable liquid to the same final volume (0.4 ml to 0.6 ml if mice are used for the test or 4.0 ml if guinea-pigs are used). Allow the mixtures to stand at room temperature for 60 min. Using not fewer than two animals for each mixture, inject the chosen volume subcutaneously into each animal. Observe the animals for 96 h and make daily records of the degree of tetanus developing in each group of animals. Repeat the test at least once and calculate the test dose as the mean of the different tests. The test dose of the toxin is the amount present in that mixture which causes tetanic paralysis in one half of the total number of animals injected with it.

When the test dose of the toxin has been determined a concentrated solution of the test toxin may be prepared in a mixture consisting of 1 volume of a 9 g/l solution of *sodium chloride R* and 1 or 2 volumes of *glycerol R*. This concentrated solution may be stored frozen and diluted as required. The specific activity of such a solution should be redetermined at frequent intervals.

Determination of the potency of the antitoxin to be examined

Preliminary test. Measure or weigh a quantity of the test toxin and dilute with or dissolve in a suitable liquid so that the solution contains five test doses per millilitre (solution of the test toxin). Prepare mixtures of the solution of the test toxin and the antitoxin to be examined so that for each mixture the volume chosen for injection contains the test dose of toxin and one of a series of graded volumes of the antitoxin to be examined. Adjust each mixture to the same final volume with a suitable liquid. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than two animals for each mixture, inject the chosen volume subcutaneously into each animal. Observe the animals for 96 h and make daily records of the degree of tetanus developing in each group of animals. Using the results, select suitable mixtures for the final test.

Final test. Prepare mixtures of the solution of the test toxin and the antitoxin to be examined so that for each mixture the volume chosen for the injection contains the test dose of toxin and one of a series of graded volumes of the antitoxin to be examined, separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined in the preliminary test. Prepare further mixtures with the same amount of test toxin and graded volumes of the reference preparation, centred on 0.1 IU in the volume chosen for injection, to confirm the test dose of the toxin. Adjust each mixture to the same final volume with a suitable liquid. Allow the mixtures to stand at room temperature for

60 min. Using not fewer than two animals for each mixture, inject the chosen volume subcutaneously into each animal. Observe the animals for 96 h and make daily records of the degree of tetanus developing in each group of animals. The test mixture which contains 0.1 IU in the volume injected is that mixture which causes tetanic paralysis in the same, or almost the same, number of animals as the reference mixture containing 0.1 IU in the volume injected.

Repeat the determination at least once and calculate the mean of all valid estimates. Estimates are valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits ($P = 0.95$) have been estimated to be:
85 per cent and 114 per cent when 2 animals per dose are used,
91.5 per cent and 109 per cent when 3 animals per dose are used,
93 per cent and 108 per cent when 6 animals per dose are used.

LABELLING

The label states whether the product consists of crude or concentrated serum.

01/2005:1492 CHEMICAL PURITY

AMMONIA (^{13}N) INJECTION**Ammoniae (^{13}N) solutio iniectionis****DEFINITION**

Ammonia (^{13}N) injection is a sterile solution of [^{13}N]ammonia for diagnostic use. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared nitrogen-13 radioactivity at the date and time stated on the label. Not less than 99 per cent of the total radioactivity corresponds to nitrogen-13 in the form of [^{13}N]ammonia. Not less than 99.0 per cent of the total radioactivity corresponds to nitrogen-13.

PRODUCTION**RADIONUCLIDE PRODUCTION**

Nitrogen-13 is a radioactive isotope of nitrogen which may be produced by various nuclear reactions, such as proton irradiation of carbon-13 or oxygen-16, or deuteron irradiation of carbon-12.

RADIOCHEMICAL SYNTHESIS

[^{13}N]Ammonia may be prepared by proton irradiation of water followed by the reduction of the resulting [^{13}N]nitrates/nitrites mixture with a reducing agent. The [^{13}N]ammonia formed is distilled from the reaction mixture and trapped in a slightly acidic solution.

Other methods may produce [^{13}N]ammonia “in-target” by proton irradiation of water containing a small amount of ethanol or acetic acid, or by proton irradiation of a slurry of [^{13}C]carbon powder in water. The resulting solution can be purified, to remove radionuclidic and radiochemical impurities, using anion and cation exchange columns.

CHARACTERS

A clear, colourless solution.

Nitrogen-13 has a half-life of 9.96 min and emits positrons with a maximum energy of 1.198 MeV, followed by annihilation gamma radiation of 0.511 MeV.

IDENTIFICATION

- Record the gamma-ray spectrum using a suitable instrument. The only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.
- It complies with test (a) for radionuclidic purity (see Tests).
- Examine the chromatograms obtained in the test for radiochemical purity. The principal peak in the radiochromatogram obtained with the test solution has approximately the same retention time as the principal peak in the radiochromatogram obtained with the reference solution.

TESTS

pH (2.2.3). The pH of the injection is 5.5 to 8.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations* (0125). The injection may be released for use before completion of the test.

Bacterial endotoxins (2.6.14): less than 175/V IU/ml, V being the maximum recommended dose in millilitres. The injection may be released for use before completion of the test.

Aluminium. In a test-tube about 12 mm in internal diameter, mix 1 ml of *acetate buffer solution pH 4.6 R* and 2 ml of a 1 in 20 dilution of the preparation to be examined in *water R*. Add 0.05 ml of a 10 g/l solution of *chromazurol S R*. After 3 min, the colour of the solution is not more intense than that of a standard prepared at the same time and in the same manner using 2 ml of a 1 in 20 dilution of *aluminium standard solution (2 ppm Al) R* (2 ppm).

The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

(a) *Half-life.* The half-life is between 9 min and 11 min.

(b) *Gamma emitting impurities.* Retain a sample of the preparation to be examined for 2 h. Examine the gamma-ray spectrum of the decayed material for the presence of radionuclidic impurities, which should, where possible, be identified and quantified. The total gamma radioactivity due to these impurities does not exceed 1.0 per cent of the total radioactivity.

The injection may be released for use before completion of tests (a) and (b).

RADIOCHEMICAL PURITY

Examine by liquid chromatography (2.2.29).

Test solution. The preparation to be examined.

Reference solution. Dilute 1.0 ml of *dilute ammonia R2* to 10.0 ml with *water R*.

The chromatographic procedure may be carried out using:

- a column 0.04 m long and 4.0 mm in internal diameter packed with *cation exchange resin R* (10 μm),
- as mobile phase at a flow rate of 2 ml/min 0.002 M *nitric acid*,
- a suitable radioactivity detector,
- a conductivity detector,
- a loop injector,

maintaining the column at a constant temperature between 20 °C and 30 °C.

Inject separately the test solution and the reference solution. The chromatogram obtained with the radioactivity detector and the test solution shows a principal peak with approximately the same retention time as the peak in the chromatogram obtained with the reference solution and the conductivity detector. Not less than 99 per cent of the total radioactivity corresponds to nitrogen-13 in the form of ammonia.

The injection may be released for use before completion of the test.

RADIOACTIVITY

Measure the radioactivity using suitable equipment by comparison with a standardised fluorine-18 solution or by using an instrument calibrated with the aid of such a solution. Standardised fluorine-18 solutions are available from laboratories recognised by the competent authority.

IMPURITIES

- [^{13}N]O₂⁻,
- [^{13}N]O₃⁻,
- [18F⁻],
- H₂[¹⁵O].

01/2005:1607 *Injection*: test sample, reference gas (b).**CARBON MONOXIDE (¹⁵O)****Carbonei monoxidum (¹⁵O)****DEFINITION**

Mixture of carbon [¹⁵O]monoxide in the gaseous phase and a suitable vehicle such as *Medicinal air (1238)*, for diagnostic use.

Purity:

- minimum 99 per cent of the total radioactivity corresponds to oxygen-15,
- minimum 97 per cent of the total radioactivity corresponds to oxygen-15 in the form of carbon monoxide (CO).

PRODUCTION**RADIONUCLIDE PRODUCTION**

Oxygen-15 is a radioactive isotope of oxygen which may be produced by various nuclear reactions such as proton irradiation of nitrogen-15 or deuteron irradiation of nitrogen-14.

RADIOCHEMICAL SYNTHESIS

In order to recover oxygen-15 as molecular oxygen from the nitrogen target gas, carrier oxygen is added at concentrations generally ranging from 0.2 per cent V/V to 1.0 per cent V/V. After irradiation, the target gas is usually reacted with activated charcoal at a temperature of about 950 °C. The activated charcoal is preconditioned before use by flushing an inert gas at the production flow rate at a temperature of about 950 °C for not less than 1 h. The carbon [¹⁵O]monoxide obtained is purified by passage through a carbon dioxide scavenger, such as soda lime, before mixing with the vehicle.

CHARACTERS

Appearance: colourless gas.

Half-life and nature of radiation of oxygen-15: see Table of physical characteristics of radionuclides (5.7).

IDENTIFICATION**A. Gamma spectrometry.**

Results: the only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. It complies with the test for radionuclidic purity (see Tests).**C. Examine the chromatograms obtained in the test for radiochemical purity.**

Results: the principal peaks in the chromatogram obtained with the test gas using the radioactivity detector are similar in retention times to the principal peaks corresponding to carbon monoxide in the chromatogram obtained with reference gas (a) using the thermal conductivity detector.

TESTS

The following tests are performed on carbon [¹⁵O]monoxide as described under radiochemical synthesis before mixing with the vehicle.

Carbon monoxide. Gas chromatography (2.2.28) as described in the test for radiochemical purity.

The concentration of carbon monoxide in the test sample is determined before administration and is used to calculate the amount of carbon monoxide to be administered to the patient.

Examine the chromatogram obtained with the thermal conductivity detector and calculate the content of carbon monoxide.

RADIONUCLIDIC PURITY

Oxygen-15: minimum 99 per cent of the total radioactivity.

A. Gamma spectrometry.

Comparison: standardised fluorine-18 solution, or by using an instrument calibrated with the aid of such a solution. Standardised fluorine-18 solutions and/or standardisation services are available from the competent authority.

Results: the spectrum obtained with the solution to be examined does not differ significantly from that obtained with a standardised fluorine-18 solution.

B. Half-life: 1.9 min to 2.2 min.

The preparation may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Carbon [¹⁵O]monoxide. Gas chromatography (2.2.28): use the normalisation procedure.

Test sample. Carbon [¹⁵O]monoxide as described under radiochemical synthesis.

Reference gas (a). Nitrogen gas mixture R.

Reference gas (b). Nitrogen R, containing 2.0 per cent V/V of carbon monoxide R1.

Column:

- *size*: *l* = 1.8 m, Ø1 = 6.3 mm and Ø2 = 3.2 mm,
- *stationary phase*: GC concentric column R,
- Carrier gas*: helium for chromatography R.

Flow rate: 65 ml/min.

Temperature:

- *column*: 40 °C,
- *injection port*: 40 °C,
- *thermal conductivity detector*: 70 °C.

Detection: thermal conductivity detector and radioactivity detector connected in series.

Injection: loop injector.

Run time: 10 min.

Retention times: oxygen, nitrogen and carbon monoxide eluting from the inner column = about 0.4 min; carbon dioxide eluting from the inner column = about 0.8 min; oxygen eluting from the outer column = about 2.1 min; nitrogen eluting from the outer column = about 3.1 min; carbon monoxide eluting from the outer column = about 6.2 min.

System suitability: reference gas (a):

- 5 clearly separated principal peaks are observed in the chromatogram obtained using the thermal conductivity detector,
- *resolution*: minimum of 1.5 between the peaks due to carbon dioxide eluting from the inner column and oxygen eluting from the outer column, in the chromatogram obtained using the thermal conductivity detector.

Limits: examine the chromatogram obtained with the radioactivity detector and calculate the percentage content of oxygen-15 substances from the peak areas.

- *carbon [¹⁵O]monoxide*: minimum 97 per cent of the total radioactivity.
- *disregard* the first peak corresponding to components co-eluting from the inner column.

RADIOACTIVITY

The radioactive concentration is determined before administration.

Measure the radioactivity using suitable equipment by comparison with a standardised fluorine-18 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2005:0266

CHROMIUM (^{51}Cr) EDETATE INJECTION

Chromii (^{51}Cr) edetatis solutio iniectionabilis

DEFINITION

Chromium (^{51}Cr) edetate injection is a sterile solution containing chromium-51 in the form of a complex of chromium(III) with ethylenediaminetetraacetic acid, the latter being present in excess. It may be made isotonic by the addition of sodium chloride and may contain a suitable antimicrobial preservative such as benzyl alcohol. Chromium-51 is a radioactive isotope of chromium and may be prepared by the neutron irradiation of chromium, either of natural isotopic composition or enriched in chromium-50. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared chromium-51 radioactivity at the date and hour stated on the label. Not less than 95 per cent of the radioactivity corresponds to chromium-51 in the form of chromium edetate. The injection contains a variable quantity of chromium (Cr) not exceeding 1 mg per millilitre.

CHARACTERS

A clear, violet solution.

Chromium-51 has a half-life of 27.7 days and emits gamma radiation.

IDENTIFICATION

- Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised chromium-51 solution. Standardised chromium-51 solutions are available from laboratories recognised by the competent authority. The gamma photon has an energy of 0.320 MeV.
- Examine the electropherogram obtained in the test for radiochemical purity. The distribution of radioactivity contributes to the identification of the preparation.

TESTS

pH (2.2.3). The pH of the solution is 3.5 to 6.5.

Chromium. Prepare a reference solution (1 mg per millilitre of Cr) as follows: dissolve 0.96 g of *chromic potassium sulphate R* and 2.87 g of *sodium edetate R* in 50 ml of *water R*, boil for 10 min, cool, adjust to pH 3.5 to 6.5 using *dilute sodium hydroxide solution R* and dilute to 100.0 ml with *water R*. Measure the absorbance (2.2.25) of the injection to be examined and the reference solution at the absorption maximum at 560 nm. The absorbance of the injection to be examined is not greater than that of the reference solution.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised chromium-51 solution.

RADIOCHEMICAL PURITY

Examine by zone electrophoresis (2.2.31), using a paper strip as the support and a solution containing 0.2 g/l of *barbital sodium R* and 10 g/l of *sodium nitrate R* as the electrolyte solution. A paper with the following characteristics is suitable: mass per unit area 120 g/m²; thickness 0.22 mm; capillary rise 105 mm to 115 mm per 30 min.

Apply to the paper 10 µl of the injection as a 3 mm band at a position 10 cm from the cathode. Apply an electric field of about 30 V per centimetre for 30 min using a stabilised current. [^{51}Cr]chromium edetate moves about 5 cm towards the anode. [^{51}Cr]Chromate moves about 10 cm towards the anode and [^{51}Cr]chromic ion moves about 7 cm towards the cathode. Determine the distribution of the radioactivity using a suitable detector. Not less than 95 per cent of the total radioactivity is found in the band corresponding to [^{51}Cr]chromium edetate.

RADIOACTIVITY

Measure the radioactivity using suitable equipment by comparison with a standardised chromium-51 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2005:0710

CYANOCOBALAMIN (^{57}Co) CAPSULES

Cyanocobalamini (^{57}Co) capsulae

DEFINITION

Cyanocobalamin (^{57}Co) capsules contain [^{57}Co]- α -(5,6-dimethylbenzimidazol-1-yl)cobamide cyanide and may contain suitable auxiliary substances. Cobalt-57 is a radioactive isotope of cobalt and may be produced by proton irradiation of nickel. Cyanocobalamin (^{57}Co) may be prepared by the growth of suitable micro-organisms on a medium containing (^{57}Co) cobaltous ion. Not less than 90 per cent of the cobalt-57 is in the form of cyanocobalamin. The capsules comply with the requirements for hard capsules in the monograph on *Capsules (0016)*, unless otherwise justified and authorised.

CHARACTERS

Hard gelatin capsules.

Cobalt-57 has a half-life of 271 days and emits gamma radiation.

IDENTIFICATION

- Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised cobalt-57 solution. Standardised cobalt-57 and cobalt-58 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of cobalt-57 has an energy of 0.122 MeV.
- Examine the chromatograms obtained in the test for radiochemical purity. The principal peak in the radio-chromatogram obtained with the test solution has a retention time similar to that of the peak in the chromatogram obtained with the reference solution.

TESTS

01/2005:0269

Disintegration. The capsules comply with the test for disintegration of tablets and capsules (2.9.1) except that one capsule is used in the test instead of six.

Uniformity of content. Determine by measurement in a suitable counting assembly and under identical geometrical conditions the radioactivity of each of not less than ten capsules. Calculate the average radioactivity per capsule. The radioactivity of no capsule differs by more than 10 per cent from the average. The relative standard deviation is less than 3.5 per cent.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument calibrated with the aid of standardised cobalt-57 and cobalt-58 solutions. The spectrum does not differ significantly from that of the standardised cobalt-57 solution. Determine the relative amounts of cobalt-57, cobalt-56 and cobalt-58 present. Cobalt-56 has a half-life of 78 days and its presence is shown by gamma photons of energy 0.847 MeV. Cobalt-58 has a half-life of 70.8 days and its presence is shown by gamma photons of energy 0.811 MeV. Not more than 0.1 per cent of the total radioactivity is due to cobalt-56, cobalt-58 and other radionuclidic impurities.

RADIOCHEMICAL PURITY

Examine by liquid chromatography (2.2.29).

Test solution. Dissolve the contents of a capsule in 1.0 ml of *water R* and allow to stand for 10 min. Centrifuge at 2000 r/min for 10 min. Use the supernatant.

Reference solution. Dissolve 10 mg of *cyanocobalamin CRS* in the mobile phase and dilute to 100 ml with the mobile phase. Dilute 2 ml of the solution to 100 ml with the mobile phase. Use within 1 h.

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4 mm in internal diameter packed with *octylsilyl silica gel for chromatography R* (5 µm),
- as mobile phase at a flow rate of 1.0 ml/min a mixture prepared as follows: mix 26.5 volumes of *methanol R* and 73.5 volumes of a 10 g/l solution of *disodium hydrogen phosphate R* adjusted to pH 3.5 using *phosphoric acid R* and use within 2 days,
- a radioactivity detector adjusted for cobalt-57,
- as detector a spectrophotometer set at 361 nm,
- a loop injector.

Inject 100 µl of the test solution and record the chromatogram for three times the retention time of cyanocobalamin. Determine the peak areas and calculate the percentage of cobalt-57 present as cyanocobalamin. Inject 100 µl of the reference solution and record the chromatogram for 30 min.

RADIOACTIVITY

The average radioactivity determined in the test for uniformity of content is not less than 90.0 per cent and not more than 110.0 per cent of the declared cobalt-57 radioactivity, at the date stated on the label.

STORAGE

Store in an airtight container, protected from light, at a temperature of 2 °C to 8 °C.

CYANOCOBALAMIN (⁵⁷Co) SOLUTION**Cyanocobalamini (⁵⁷Co) solutio****DEFINITION**

Cyanocobalamin (⁵⁷Co) solution is a solution of [⁵⁷Co]-α-(5,6-dimethylbenzimidazol-1-yl)cobamide cyanide and may contain a stabiliser and an antimicrobial preservative. Cobalt-57 is a radioactive isotope of cobalt and may be produced by the irradiation of nickel with protons of suitable energy. Cyanocobalamin (⁵⁷Co) may be prepared by the growth of suitable micro-organisms on a medium containing (⁵⁷Co) cobaltous ion. The solution contains not less than 90.0 per cent and not more than 110.0 per cent of the declared cobalt-57 radioactivity at the date stated on the label. Not less than 90 per cent of the cobalt-57 is in the form of cyanocobalamin.

CHARACTERS

A clear, colourless or slightly pink solution. Cobalt-57 has a half-life of 271 days and emits gamma radiation.

IDENTIFICATION

- A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised cobalt-57 solution. Standardised cobalt-57 and cobalt-58 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of cobalt-57 has an energy of 0.122 MeV.
- B. Examine the chromatograms obtained in the test for radiochemical purity. The principal peak in the radiochromatogram obtained with the solution to be examined has a retention time similar to that of the peak in the chromatogram obtained with the reference solution.

TESTS

pH (2.2.3). The pH of the solution is 4.0 to 6.0.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument calibrated with the aid of standardised cobalt-57 and cobalt-58 solutions. The spectrum does not differ significantly from that of the standardised cobalt-57 solution. Determine the relative amounts of cobalt-57, cobalt-56 and cobalt-58 present. Cobalt-56 has a half-life of 78 days and its presence is shown by gamma photons of energy 0.847 MeV. Cobalt-58 has a half-life of 70.8 days and its presence is shown by gamma photons of energy 0.811 MeV. Not more than 0.1 per cent of the total radioactivity is due to cobalt-56, cobalt-58 and other radionuclidic impurities.

RADIOCHEMICAL PURITY

Examine by liquid chromatography (2.2.29).

Reference solution. Dissolve 10 mg of *cyanocobalamin CRS* in the mobile phase and dilute to 100 ml with the mobile phase. Dilute 2 ml of the solution to 100 ml with the mobile phase. Use within 1 h.

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4 mm in internal diameter packed with *octylsilyl silica gel for chromatography R* (5 µm),

- as mobile phase at a flow rate of 1.0 ml/min a mixture prepared as follows: mix 26.5 volumes of *methanol R* and 73.5 volumes of a 10 g/l solution of *disodium hydrogen phosphate R* adjusted to pH 3.5 using *phosphoric acid R* and use within 2 days,
- a radioactivity detector adjusted for cobalt-57,
- as detector a spectrophotometer set at 361 nm,
- a loop injector.

Inject 100 µl of the solution to be examined and record the chromatogram for three times the retention time of cyanocobalamin. Determine the peak areas and calculate the percentage of cobalt-57 present as cyanocobalamin. Inject 100 µl of the reference solution and record the chromatogram for 30 min.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised cobalt-57 solution.

STORAGE

Store protected from light at a temperature of 2 °C to 8 °C.

01/2005:1505

CYANOCOBALAMIN (^{58}Co) CAPSULES

Cyanocobalamini (^{58}Co) capsulae

DEFINITION

Cyanocobalamin (^{58}Co) capsules contain [^{58}Co]- α -(5,6-dimethylbenzimidazol-1-yl)cobamide cyanide and may contain suitable auxiliary substances. Cobalt-58 is a radioactive isotope of cobalt and may be produced by neutron irradiation of nickel. Cyanocobalamin (^{58}Co) may be prepared by the growth of suitable micro-organisms on a medium containing (^{58}Co) cobaltous ion. Not less than 84 per cent of the cobalt-58 is in the form of cyanocobalamin. The capsules comply with the requirements for hard capsules in the monograph on *Capsules (0016)*, unless otherwise justified and authorised. The average radioactivity is not less than 90.0 per cent and not more than 110.0 per cent of the declared cobalt-58 radioactivity at the date stated on the label.

CHARACTERS

Hard gelatin capsules.

Cobalt-58 has a half-life of 70.9 days and emits beta (β^+) radiation and gamma radiation.

IDENTIFICATION

- Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised cobalt-58 solution. Standardised cobalt-58 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photons of cobalt-58 have energies of 0.511 MeV (annihilation radiation) and 0.811 MeV.
- Examine the chromatograms obtained in the test for radiochemical purity. The principal peak in the radiochromatogram obtained with the test solution has a retention time similar to that of the peak in the chromatogram obtained with the reference solution.

TESTS

Disintegration. The capsules comply with the test for disintegration of tablets and capsules (2.9.1) except that one capsule is used in the test instead of six.

Uniformity of content. Determine by measurement in a suitable counting assembly and under identical geometrical conditions the radioactivity of each of not less than ten capsules. Calculate the average radioactivity per capsule. The radioactivity of no capsule differs by more than 10 per cent from the average. The relative standard deviation is less than 3.5 per cent.

RADIONUCLIDIC PURITY
